The RF amplifier, mixer, and first IF amplifier stages are series fed and controlled by AGC voltage taken from the detector diode. (The second IF amplifier stage is self-biased and is not controlled by AGC voltage.) R1 is the detector load resistor and capacitor C1 is the RF bypass capacitor for R1. Resistor R2 and capacitor C2 form an RC network to filter the AGC voltage obtained from the detector. Resistor R3 and capacitor C3 form a decoupling network for the mixer stage; similarly, resistor R4 and capacitor C4 form a decoupling network for the RF amplifier stage.

The time constant of the RC filter is long enough to remove the lowest modulation frequencies from the d-c voltage, but short enough that the d-c bias level changes in response to moderately rapid changes in received signal strength (due to signal fluctuations, fading, etc.). The simple AGC circuit is employed in many typical AM superheterodyne receivers which use a diode type detector; it is also employed in some FM receivers which use a ratio-type detector.

AT.178

Figure 10-26.–Simple AGC system.

Delayed AGC

The term delayed AGC is used to denote a voltage delay, and should not be confused with a time delay. The simple AGC system just described is effective on all received signals, from the weakest to the strongest. It has the disadvantage of developing an AGC voltage even for very weak received signals. As a result, the sensitivity of the receiver to weak signals is reduced considerably. In order to increase sensitivity and enable the receiver to respond to weak signals, it is desirable to provide a means of delaying the application of AGC voltage until the received signal reaches a predetermined value, sometimes called the threshold level of AGC. Figure 10-27 illustrates a typical delayed AGC system.

The delayed AGC system makes use of a fixed delay voltage applied to a separate AGC detector. The delayed AGC detector must be a separate diode, independent of the signal detector (demodulator) because the fixed delay voltage prevents the AGC detector diode from rectifying an RF signal until the signal level exceeds the value of the delay voltage. (If separate diodes were not used, the delay voltage would prevent the detector diode from rectifying weak signals below the threshold level established by the value of the delay voltage.) Once the signal level exceeds the value of the delay voltage, the AGC detector begins to rectify the signal, and produces a d-c output voltage which is then applied as bias to the controlled stages. Filtering of the d-c output voltage removes amplitude modulation components; the RC time constant considerations are essentially the same as for the simple AGC system. The delayed AGC circuit is employed in many AM superheterodyne receivers, as well as in microwave and radar receiving systems.

Amplified and Delayed AGC

There are many variations in amplified and delayed AGC systems. However, these can be classified according to two categories: systems

AT.179

Figure 10-27.–Delayed AGC system.

13449

The position of the fingers after the rotation is shown in Fig. 4. The pencil line can be brightened, if necessary, by making additional turns. Circles up to perhaps 3 inches in diameter can be drawn with the legs of the compass straight, but for larger sizes, both the needle-point leg and the pencil or pen leg should be bent at the knuckle joints so as to be perpendicular to the paper (Fig. 5). The 6-inch compass may be used in this way for circles up to perhaps 10 inches in diameter; larger circles are made by using the lengthening bar, as illustrated in Fig. 6.

FIG. 4

FIG. 5

FIG. 6

which amplify a signal before rectification to obtain the AGC voltage, and systems which amplify the AGC voltage after signal rectification. In either case, a form of delayed voltage is incorporated so that the maximum sensitivity of the receiver can be realized for weak signal reception. When amplified and delayed AGC is used to control a receiving system, the overall output versus signal input characteristics can be made to approach an almost ideal condition.

Figure 10-28 shows block diagrams for two basic types of amplified and delayed AGC systems. Section (A) of the figure shows a system in which the signal is amplified by an AGC IF amplifier before rectification by the AGC diode. Section (B) shows a system in which the signal voltage is amplified by a d-c amplifier after rectification by the AGC diode. The d-c amplifier stage is followed by a delay diode. AGC voltage is supplied to the controlled stages only when the diode's cathode is negative with respect to its plate, and the diode conducts. When the delay diode is not conducting, the AGC output voltage is zero and the receiver gain is at maximum for signals below the threshold of AGC operation.

The delay voltage is applied to the AGC detector, which follows a separate amplifier. The AGC IF amplifier receives its signal from the last IF amplifier of the receiving system.

A variation of this AGC system employs an independent AGC amplifier channel consisting of several stages with greater overall amplification (gain) than does the signal IF amplifier channel. In the system illustrated in (B), the delay voltage is applied to the d-c amplifier stage. Almost all AGC circuits using a d-c amplifier to control the AGC voltage employ a delay diode in the output to prevent the d-c output voltage from ever becoming positive with respect to ground.

AFC

Automatic frequency control (AFC) systems are commonly incorporated into radio or radar

AT.180

Figure 10-28.–Amplified and delayed AGC systems.

13450

receiving circuitry. The purpose of an AFC system is to maintain the appropriate operating frequency of the local oscillator. Oscillators in the UHF and microwave regions have generally poor frequency stability; this instability is often caused by factors which are negligible at lower frequency ranges. Among the major factors are the following:

1. Physical size. The frequency-determining components are necessarily small. Any condition that changes their shape or size causes a change in frequency. Such conditions include vibration, thermal expansion, etc.

2. Frequency pulling. Changes in load cause changes in energy reflections, which effectively means a change in the nature of circuit impedance. The reactive component of the impedance change is combined with the frequency-determining reactances. Thus the operating frequency is also changed. Changes in load may result from such factors as changes in the characteristics of transmission lines, or from reflected energy (echoes) from nearby objects (such as sea return, ECM chaff, aircraft structures, the radome, etc.). Reflected energy changes may also result from variations of the surrounding air (density, moisture content, temperature, etc.).

3. Voltage variations. These variations may be caused either by fluctuations in the primary power source or by poor regulation in the power supply unit of the system.

Because of the inherent frequency instability, it is important that tuning of microwave oscillators be accomplished automatically. For this reason, some type of AFC system is incorporated in all airborne radar sets, and in many other classes of microwave receivers and transmitters. AFC systems are classified in three ways, all according to some aspect of operation. One classification divides AFC systems into single mixer or double mixer classes. A second classification distinguishes the hunting and nonhunting classes. The other classification is according to "absolute frequency" or "frequency difference" operation.

Chapter 11 of this manual, in connection with microwave mixers, contains some information on single ended and double ended mixers. A comparison of that discussion and the information in the present chapter could produce some confusion. As occasionally happens, the same or similar words are used in the classification of two different types of systems. The present discussion is concerned with the operation of AFC systems, which include mixers; the chapter 11 discussion is concerned with the operation of the mixer itself.

All AFC systems require the use of some form of discriminator to detect frequency differences between the oscillator and the reference frequency standard. Also required in all AFC systems is a control circuit to compensate for the difference by shifting the oscillator's frequency.

The type circuitry and provisions for control used in a given set depend on the particular type and specific application of the system.

The following paragraphs present a very brief summary of some important considerations for each of the six basic classes of AFC systems.

Single Mixer

In a single mixer AFC system (fig. 10-29) a portion of the transmitter output is leaked into the mixer, where it beats with the local oscillator signal. The difference frequency (the IF signal) appears at the ouput of the mixer and is then amplified by one or more stages of IF preamplification.

At this point, the IF signal follows two paths–it is further amplified and fed to the detector, and it is also fed into the AFC discriminator. The output voltage from the discriminator varies in amplitude and polarity with changes in the applied frequency.

If the applied frequency (the IF) is at the resonant or center frequency of the discriminator circuit, the output voltage is zero. If the applied frequency is either above or below the desired frequency, the output of the discriminator is either positive or negative depending on the direction of deviation. Voltage magnitude is dependent on the amount of the frequency difference.

The output of the discriminator is then fed to either a d-c amplifier or to some other type control circuit which controls the klystron's reflector voltage. Variations in reflector voltage causes the klystron to shift its frequency of oscillation.

OCDCI
13451

AT.181

Figure 10-29.–Single mixer AFC system.

Double Mixer

Most modern radar systems utilize a double mixer AFC system such as that shown in figure 10-30. The separate signal mixer and the AFC mixer are both connected to the same local oscillator. The AFC mixer is coupled to the transmission line through an attenuator which reduces the transmitted pulse and the received echoes by the same ratio. With this arrangement, strong signals from nearby radar, jammers, or sea returns cannot affect the operation of the AFC loop. The double mixer system is similar to the single mixer system, except that the former contains an AFC attenuator and separate IF stages.

Hunting

Almost all radar sets in naval aircraft use the hunting method of AFC. Basically, the hunting system causes the oscillator to sweep through a wide frequency range–wider than the frequency variation range of the radar. This sweep of operating frequency permits the AFC system to find the correct frequency, lock on, and automatically maintain the oscillator on that frequency. This method offers the advantage of automatically locating the new frequency in the event of a sudden large frequency deviation.

Sweeping of the frequency range is usually accomplished by applying a sawtooth of voltage to the reflector of a klystron oscillator. The

AT.182

Figure 10-30.–Double mixer AFC system.

FS452 ICAL1

most commonly used sawtooth generators for this purpose are the thyratron and the phantastron, but other types may be used.

A variation of the hunting system utilizes an audiofrequency sine wave superimposed on the sawtooth. This method improves the lockon feature of the basic system and increases the speed of response to frequency shifts. Almost all AFC systems incorporates some type of lockon feature. When the oscillator is operating at the proper frequency, sweeping action is stopped and slight variations are compensated. In the event of a large sudden shift, lock is broken and sweeping is resumed.

Nonhunting

In the nonhunting system, the oscillator is manually tuned to the correct frequency and is then maintained electronically at that frequency. Usage of the nonhumting system is normally limited to equipments where transmission and reception are independent operations (such as single sideband and data link) requiring precise frequency of operation.

Although no sweeping is accomplished, a discriminator is used to detect frequency changes. The discriminator output, in turn, is used to shift the frequency of the oscillator as required, within a narrow allowable frequency range. This method is not usually used in radar systems due to the narrow allowable drift range.

Absolute Frequency

In the absolute frequency system, the operating frequency is determined by a precision frequency standard such as a high-Q cavity. This system is used to maintain the oscillator at the assigned frequency of a transmitter at some remote location. It may also be used to maintain the transmitter at an assigned frequency.

This system has the advantage of permitting reliable reception of intermittent signals with no delay while the receiver searches for the proper frequency. The disadvantage is that the transmitter and receiver must operate on the same frequency, or no reception is probable.

In order to maintain such a precise frequency, eleborate voltage regulation, isolation, and shielding provisions are required. For these reasons, airborne use of this system is not common. Even in data link applications, the frequency difference method is usually employed.

Difference Frequency

In the difference frequency system, the local oscillator is maintained on a frequency which is greater or less than the magnetron frequency. The difference in frequencies is an amount equal to the IF of the receiver. This maintains the tuning of the receiver during search operations.

In normal radar operation, the received echo is of the same frequency as the transmitted pulse (disregarding the slight Doppler shift). Therefore, a fixed tuned IF channel can be used to provide maximum gain. Bandwidth need be only wide enough to cover the normal frequency drift–hunting may be incorporated for unusual shifts.

CHAPTER 11

SPECIAL CIRCUITS AND COMPONENTS

ELECTROMECHANICAL DEVICES

In modern naval aircraft, mechanical and electrical devices for sensing changes in direction and attitude are indispensable. Among the systems which depend upon such devices for their operation are the following:

1. Gyrocompass systems.
2. Flight control systems and autopilots.
3. Radar, camera, and gun platform stabilization systems.
4. Antenna tracking rate measurement systems.
5. Inertial navigation systems.

In addition to sensing devices, aircraft systems require that indications be made available to the pilot, navigator, and operating personnel concerning the operation of many equipments and systems. Many of these indications originate in equipment which must be physically located in places not accessible to the personnel responsible for monitoring them. Electromechanical devices are frequently employed to provide these remote indications.

Among the devices discussed in this section are the synchro, the gyro, the accelerometer, and the servosystem.

SYNCHROS

A synchro is an electromechanical analog converter. It may, through inductive means, give an electrical output which is a function of its rotor position; or it may position its rotor to an angle which is a function of the electrical input. The term synchro, as it was originally used in the Navy, included a category of induction devices. The term is now used rather loosely in general application. According to the military specification, however, proper use of the term is limited to one of five types of devices, as listed below.

1. Synchro transmitter–converts a mechanical input (rotor position) into an electrical output.
2. Synchro receiver–converts an electrical input into a rotor position (mechanical output).
3. Synchro differential transmitter–gives an electrical output which is a function of two inputs, an electrical input and its rotor position.
4. Synchro differential receiver–gives a mechanical output which is a function of two electrical inputs, the primary and secondary.
5. Control transformer—gives an electrical output, with a varying magnitude and polarity, which depends on the relative position of the rotor and stator.

Theory of Operation

A basic introduction to synchros is presented in chapter 19 of Basic Electricity, NavPers 10086-B. The discussion presented in the following paragraphs is intended to summarize the basic manual and to present additional details and data of practical use to the technician.

In normal operation, a synchro can be treated as a complex transformer in which the coupling coefficient is proportional to the cosine of the angle between the primary and the secondary. All synchros use a WYE connected stator winding. The rotor is either a WYE or a single winding, depending on the device.

A synchro is a single phase, 60- or 400-hertz device. The output voltages, line to line, are either in phase or 180° out of phase with the rotor voltage. The three-line-to-line stator volt-

13454

Figure 11-1.–Electrical zeroing procedure.

ages uniquely identify a single electrical angle between 0° and 360°.

In order to identify the electrical angle, an arbitrary electrical zero (EZ) has been chosen for each device. (See fig. 11-1.) This electrical zero is an internal reference–the angle that the rotor makes with respect to the stator under specified conditions.

If a voltage of known amplitude and frequency is impressed on the rotor of a synchro, the voltages induced in the stator describe a single angle. This mechanical-to-electrical analog is the principle of the synchro transmitter. If these three voltages are applied to the stator terminals of a synchro, the voltage induced in the secondary (rotor) is proportional to the sine of the difference between the electrical angle represented by the stator voltages and the mechanical rotor angle.

In the synchro control transformer, the output voltage is normally supplied as an error signal driving a device which turns the rotor. The rotor continues to be turned until the synchro's electrical angle coincides with the input (command) angle. At this position the output voltage of the transformer drops to zero.

In the synchro receiver, the secondary (rotor) is connected to the same a-c excitation as the transmitter. The two synchros, transmitter and receiver, are connected in parallel. When both rotors make the same electrical angle, identical voltages are induced in the respective transmitter and receiver stator windings. Since the voltages are identical, no current flows in the external wires or in the stator winding; therefore, no magnetic field is induced. If the rotors do not make the same angle, the voltages induced in the transmitter stators are different

18455

from those in the receiver stators, and currents flow, creating an associated (stator) magnetic field in both synchros. The magnetic field of the rotor, interacting with the magnetic field of the stator, attempts to turn the rotor until the fields coincide. If the transmitter rotor is not permitted to turn, the receiver rotor turns until the turning force reaches zero. Both torque arm and magnitude decrease as the error angle–the difference between the transmitter and receiver angles–approaches zero. At angles near zero, only a weak magnetic field is induced by the stator currents; therefore, to prevent overshoots and resulting oscillations, receiver rotors are provided with additional mechanical damping.

The chief difference between synchro units is in rotor design; each device is designed to have the best electrical properties when connected into the system in the expected manner. Any one of them could be connected as either of the others (transmitter as receiver or transformer, etc.), but with attendant problems such as hunting or decrease in accuracy and speed.

The differential transmitter and the differential receiver have a WYE connected rotor as well as a WYE connected stator. They are designed to supply an output angle which is the sum, or difference, of two input angles; the differential transmitter combines an electrical and a mechanical angle to furnish an electrical output. The receiver combines two electrical inputs to furnish a mechanical output. As in the other synchros, the major difference between the transmitter and the receiver is in rotor construction, the receiver rotor being designed to provide increased damping.

When the stator is excited by voltages normally supplied by a synchro transmitter, voltages are induced into each of the rotor windings. The voltage induced into each secondary winding varies with mechanical displacement in the same manner as in a regular synchro, except that in this case there are three outputs, displaced 120° electrically from each other.

The primary input voltages to the stator create a resultant magnetic field. Changing the input voltages to indicate a different angle will change the orientation, but not the magnitude of the resultant field. It is thus possible to have this primary field represent any angle with respect to zero. At the same time, it is also possible to position the rotor, causing the output electrical data to be advanced an electrical angle equal to the mechanical deviation from electrical zero.

In the differential receiver, the stator and rotor fields form a magnetic couple as in the synchro receiver. (Each field inside the case may be considered as that of a simple bar magnet.) The rotor will turn, if free to do so, until the two fields are alined.

System Alinement

Since the stator is normally fixed with respect to the case, the internal reference is easily extended by turning the case until the electrical zero angle coincides with a convenient external reference point. In a particular system this point may be identified by a scribe mark, by a locking pin, by an optical sight arrangement, or by a zero reading on a dial or gage. The particular means used is not important, except that the adjustment can be repeated with greater accuracy in some kinds of systems than in others.

All synchros in a system having an external reference should be alined to that reference. Not infrequently, systems are "adjusted" by turning any intermediate device until the output indication agrees with the input. When a unit is changed, angular agreement is lost, to be regained by turning the case of a convenient synchro. This solution requires only one step to aline the synchro system each time a component of the system is changed. It may be acceptable if useful data is taken out of the system at only one point.

If a number of outputs are taken from different points in the system, it becomes imperative that the system be properly alined and that all components indicate proper angles at all times, rather than a + 15° error at one point in the system balancing a -15° error some place else in the system. This can be done either by completely alining the system, starting at a known good zero reference and working toward the final transmitter, or by establishing an external standard and insuring that all synchros are properly zeroed to this standard prior to installation. This second solution becomes very tricky if there are any mechanical linkages required in the installation; if all linkages are electrical, a synchro will automatically indicate the correct angle when installed.

13456

GYROS

Although every spinning object exhibits some gyroscopic properties, a true gyroscope is a complex item designed and mounted specifically to utilize these properties. Several types of gyros have been developed for various applications. Although each type exhibits its properties in a somewhat different manner, all operate on the same basic principle.

Basic Principles

Every object possess inertia; it tends to maintain its present position if at rest, or to continue in uniform motion if moving. A moving body also possess momentum; the amount of momentum depends on the mass of the body and its velocity. A body possessing circular motion (a revolving body) must maintain a balance of forces in order to revolve in a uniform path. A rotating mass represents a special type of revolving body, where the center of mass and the center of revolution coincide. Basically, a gyroscope is a spinning mass which has a high mass-to-size ratio and a high speed of rotation.

The spinning mass, called the rotor, is in itself the gyroscopic element. It is mounted in such a manner that the friction at all points is kept as small as possible, and is equally distributed to present balanced forces acting on the common centers of mass and rotation.

Figure 11-2 illustrates a demonstration gyro used to explain and demonstrate gyroscopic terms, principles, and operation. This figure should be used for reference throughout the following discussion of the basic gyro. (The rotor shaft mentioned previously is actually the spin axis.)

The rotor is mounted so that it is free to spin on its axis. As the rotor spins, its momentum increases with an increase in rotational speed. Each particle of the rotor which is not located on the axis of rotation possesses some momentum, depending on its mass and its linear velocity. The total momentum of the rotor is the total of the momentum forces on all particles. Figure 11-3 and the subsequent discussion show how the distribution of rotor mass affects rotor momentum. The three rotors shown are assumed to have the same specific density (mass-to-volume ratio), equal mass, and equal angular velocity.

AT.184

Figure 11-2.–Demonstration gyro.

As previously stated, momentum varies directly with both mass and linear velocity. Since in the present discussion the mass of each rotor, as well as the mass of each particle of each rotor, is assumed to be equal, mass may be disregarded in the following comparisons.

Linear velocity varies directly with the angular velocity and with the effective radius of rotation. In the current discussion, the angular velocity (revolutions per second) is assumed to be the same for each rotor, and may

AT.185

Figure 11-3.—Effect of rotor design on momentum.

13457

therefore be disregarded. Thus, for the three rotors shown in figure 11-3, a comparison can be made on the basis of the effective radius of rotation.

Rotor A (fig. 11-3) is a thin disk with a comparatively large radius and uniform thickness. In this instance, the effective radius is equal to one-half the radius of the rotor (due to the uniform distribution of particles). Rotor B also has uniform distribution of particles; but due to its shape (thick and with a comparatively small diameter), its effective radius is somewhat smaller. This rotor possesses less momentum than rotor A at the same angular velocity.

Rotor C, on the other hand, does not have a uniform distribution of its mass. Due to its shape, the particles are concentrated toward the outer rim, and the effective radius is somewhat more than one-half radius of the rotor. A rotor with this shape would normally have greater momentum than either of the others illustrated.

In effect, the momentum of the rotor acts in a plane which contains the center of rotation and the orbit of the average particle of the rotating mass (the plane of rotation).

The rotor must be built so that the plane of rotation is perpendicular to the spin axis. As shown in figure 11-2, the rotor shaft is supported by low friction bearings mounted in the rotor support. The momentum of the rotor acts to maintain rotation within the plane. It resists any attempt to change the plane of rotation by tilting the spin axis to an angle not perpendicular to the original plane. A stationary gyro is relatively free to move in any direction as long as the spin axis maintains its perpendicular relationship with respect to the original plane of rotation.

Properties of Gyroscopes

DEGREE OF FREEDOM.–A rotor mounted in a rigidly fixed support would serve no useful purpose. A practical gyro must be constructed in such a manner that the base can be maneuvered or changed with respect to the spin axis and the plane of rotation. When the base is rotated in such a direction that the plane of rotation is not changed, the gyro is said to possess FREEDOM in that direction.

Gyro freedom is provided through the use of GIMBALS (fig. 11-2). A gimbal is a supporting structure that is able to revolve so as to provide the gyro with a DEGREE OF FREEDOM. A gyro having two degrees of freedom is able to maintain its plane of rotation regardless of the movement of the base, and is called a FREE gyro. Free gyros require two gimbals.

The term "degrees" of freedom must not be confused with angular measurements. As applied to gyros, the term indicates the number of directions in which the base may be rotated without disturbing the plane of rotation.

In figure 11-2 note that each gimbal is supported through an axis which is perpendicular to the axis of the element which is supported by the gimbal. Each gimbal is mounted in low friction bearings to provide greater precision and less opposition to desired motion.

RIGIDITY.–As previously discussed, one of the basic properties of the gyroscope is its opposition to any change in its plane of rotation. It tends to maintain a fixed position in space. This property is called RIGIDITY. A gyroscope possesses rigidity because of, and in an amount directly related to, the momentum of its rotor. Gyroscopic rigidity is not absolute, however; the plane of rotation can be changed in several ways.

PRECESSION.–If a force is applied to the rotor shaft, the spin axis of the gyro may be tilted. The tilting represents rotation of the axis, and occurs in the manner shown in figure 11-4 and described in the following paragraph.

AT.186

Figure 11-4.–Gyroscopic precession.

13458 SECRET

A downward force applied to the outer gimbal at point A is transferred through pivot B to the inner gimbal, and is felt as a downward force at point C. The downward force on the inner gimbal at point C, in turn, travels 90° in the direction of rotation and causes a downward movement of the rotor at point D. This downward movement of the rotor at point D represents a rotation of the spin axis in the direction indicated by the arrow at point E. This rotation of the spin axis is called precession.

The property of precession is closely associated with the property of rigidity. The two properties are mutually dependent; a gyro does not possess rigidity if it does not precess, and a precessing gyro always offers some amount of rigidity.

The tilting force which causes a gyro to precess is called a TORQUE. It acts at some distance from the center of gravity, and has a magnitude which depends on the amount of force and the distance at which it is applied. It produces angular displacement of the spin axis (and the plane of rotation); angular displacement is a partial rotation. Precession of a gyro is always a reaction to an applied torque. (One cannot precess a gyro–one can only apply a torque that will cause a gyro to precess itself.)

A force applied to the rotor at its center of gravity does not tend to precess the gyro. A spinning gyro can be moved in any direction as readily as a gyro at rest, provided the spin axis remains parallel to its original position in space. (This type of motion is called TRANSLATIONAL motion.) Because of this feature, a gyro cannot provide stabilization in planes perpendicular to the spin axis–the gyro makes no response to motion in these directions. For complete stabilization in aircraft, two gyros, with their spin axes perpendicular to each other, are required. Motions which do not affect one gyro produce the necessary response in the other. The dual installation permits the establishment of reference lines from which any changes in pitch, yaw, or roll may be measured.

Thus far the discussion of precession has centered on the precession of a gyro as viewed in relation to its established position in space. This is referred to as REAL precession. A free gyro which is stationary with respect to a fixed point on the surface of the earth exhibits an additional property called APPARENT precession. Rigidity fixes the spin axis in space; the earth, which is rotating, revolves around the rotor. Thus, as viewed from its fixed position on the surface of the earth, the axis of the gyro appears to tilt (or precess) at a rate which corresponds to the rate of rotation of the earth about its spatial axis.

Apparent precession makes a completely free gyro unfit for use as a reference for earth-bound equipment over an extended period of time. To compensate for apparent precession, an ERECTING mechanism is normally incorporated to maintain the spin axis in a fixed position relative to the earth's surface.

DRIFT.–The gyro spin axis does not always point in the direction it theoretically should. This error in the gyro is produced by random inaccuracies in the system. The resulting change in position of the spin axis is called DRIFT. There are three general sources of drift in a gyroscope, as follows:

1. Imbalance. A gyroscope often becomes dynamically unbalanced when operating at a speed or temperature other than that for which it was designed. Some imbalance exists in any gyro since manufacturing processes do not give perfect symmetry.

2. Bearing friction. Friction in the bearings of the gimbals results in lost energy and incorrect gimbal positions. Friction in the spin axis bearing causes drift only if the friction is not symmetrical; an even amount of friction all around in a bearing results only in a change of the rate of rotation.

3. Inertia of gimbals. Energy is lost whenever a gimbal rotates because of the inertia of the gimbal. The greater the mass of the gimbal, the greater the drift from this source.

Complete elimination of drift in gyroscopes appears to be impossible. However, great strides have been made in recent years twoard reducing the amount.

Types of Gyros

A gyro is a bilateral device. If a torque is applied, the gyro precesses at an angular rate proportional to the magnitude of the applied torque. If a gyro is caused to precess at an angular rate, the gyro develops a torque which is proportional to the rate of precession. This feature indicates the two basic types of gyros–distinguished mainly by the input and output devices.

STAGI 13459

The bow instruments are used for small circles, particularly when a number are to be made of the same diameter. Small adjustments should be made with one hand with the needle point in position on the paper (Fig. 7).

FIG. 7

There is no doubt that continuous practice in the proper use of a compass will greatly improve the technique of using it. Repeated exercises in the use of a compass will aid the beginning draftsman immeasurably.

ASSIGNMENT:

1. Draw a horizontal line through the approximate center of your drawing paper. On it, mark off radii for 8 concentric circles $\frac{1}{4}$ inch apart. Draw the smallest circle first. See illustration.

2. Draw a 2-inch square in the approximate center of your drawing paper. Identify points A, B, C, D, E, as shown. Divide AE into 4 $\frac{1}{4}$-inch spaces, using your scale. With compass and centers A, B, C, and D, draw 4 semicircles with a $\frac{1}{4}$-inch radius, 4 with a $\frac{1}{2}$-inch radius, etc. Complete the figure by drawing the horizontal and vertical lines as shown. Be sure to use your triangles and T-square.

1348

DISPLACEMENT GYRO.–This type of gyro is used to measure angular displacement of the base mounting from an established reference line. The reference line is established by the spin axis and is maintained fixed by the rigidity of the gyro. In aircraft gyro systems, motion of the aircraft with respect to sensitive axes (roll, pitch, and/or yaw) results in angular displacement of the gimbals with respect to the spin axis and plane of rotation. Angular displacement is measured by means of synchros, potentiometers, capacitive or inductive bridges, etc. The device used to detect angular displacement and develop the error signal is called a PICKOFF.

RATE GYRO.–A rate gyro usually has a single degree of freedom, and is subjected to an angular rate about its sensitive axis as illustrated in figure 11-5. In response to displacement in the sensitive (quadrature) axis, the gyro develops a torque which is proportional to the rate of angular displacement. Instead of allowing complete freedom of motion about the gimbal axis, the rate gyro has a restraining device (spring). The gimbal is able to rotate about its axis only until the restraining force becomes equal to the torque developed by the gyro. A pickoff arranged to measure the angular displacement of the gimbal axis may be used to measure the angular rate of the input.

AT.187

Figure 11-5.–Simplified rate gyro.

ACCELEROMETERS

Accelerometers have been used for many years, but until the last few decades they were used mainly in laboratories. They are now in common use as a means to measure an aircraft's rate of change or deviation from its planned course. They are used in conjunction with autopilots, inertial navigation systems, etc. They are also used to help the pilot land his aircraft by indicating the vertical acceleration. An additional use of the accelerometer is to judge the amount of dynamic and aerodynamic force imposed upon the pilot.

Acceleration can be defined as the rate of change of velocity of a moving object with respect to time. Velocity is the rate of change of distance with respect to time.

An example of a simple accelerometer is shown in figure 11-6. Although this is a simplified version, the basic accelerometer principles may be observed. When there is no acceleration (as shown in (A)), the two springs attached to the mass maintain the mass in the center, or null, position. Therefore, the meter indication is zero.

If an application of force causes the accelerometer housing to move suddenly from left to right, the mass (conforming to Newton's law) tends to remain stationary. This causes the meter needle to pivot about its axis and give the indication shown in (B). When the force is no longer applied, the springs again center the mass and the meter returns to zero. Conversely, if the force is applied from the opposite direction, the same principle causes the mass to react in the same manner, but with the opposite indication on the meter. The damper pistons and cylinders

AT.188

Figure 11-6.–Simplified accelerometer.

prevent vibration and over sensitivity of the accelerometer by damping transient movements.

Vertical Reference Accelerometer

Figure 11-7 is a mechanical schematic of a vertical reference accelerometer currently used in naval aircraft. The three pointers on the face of the dial indicate instantaneous negative or positive vertical acceleration as well as the maximum acceleration in either direction during any selected period of time. With the aircraft in level flight, the instantaneous acceleration pointer reads positive 1 G.

As illustrated in the schematic, vertical movement of the mass causes the cord-pulley assembly to move. This turns the main pointer shaft and rotates the main pointer. As the shaft rotates, the main pointer driver arm moves toward one of the auxiliary pointer driver arms. If the G force is larger than any previously encountered, the two driver arms make contact

and the auxiliary pointer is driven in coincidence with the main pointer.

As the auxiliary pointer rotates, the pawl slides over the ratchet teeth; but when the G forces start to diminish, the pawl engages one of the ratchet teeth and holds the auxiliary pointer at its maximum excursion of travel. This indicates the maximum G force in that particular direction. The RESET knob on the face of the instrument allows the pointers to be returned to the null position when desired. It should be noted that the direction of vertical acceleration determines which auxiliary pointer will rotate.

Force Balance Accelerometer

An accelerometer commonly used with inertial navigation systems is the force balance accelerometer. A schematic representation of this type is shown in figure 11-8. The pickoff coil, the mass, and the torquer coils are all situated on a common movable shaft, which has the ability to make a partial rotation about its pivot point axis.

With zero acceleration, the induced current in the pickoff coil is balanced and the torquer coils keep the mass in the null position. However, as acceleration occurs, the mass velocity tends to remain constant. Since the stationary portion of the accelerometer assumes the new velocity, it causes one of the exciter coils to move closer to the pickoff coil and the other exciter coil to move farther away. Which exciter coil comes nearer to the pickoff coil depends upon the direction of acceleration. As the distance changes between the exciter coils and the pickoff coil, an unbalanced condition occurs in the pickoff coil circuit. This causes an error signal to be induced, which is amplified, changed to d.c., and applied to the torquer coils. Windings of all the coils are such that any unbalanced condition in the circuits produces a bucking (or reverse) current which counteracts the field of the torquer magnets and keeps the mass near mechanical zero. As the acceleration force increases, the amount of current necessary to keep the mass near the null position also increases. Since the current is proportional to the acceleration, the voltage drop across Rp, a precision resistor, is also indicative of acceleration. This voltage drop, E_{R_p}, then becomes the electrical output from the accelerometer. It can then be supplied to flight control systems as a function of acceleration.

AT.189

Figure 11-8.–Force balance accelerometer.

Pulse Counting Accelerometer

Though the output of a force balance accelerometer is an analog current proportional to acceleration, there is need for accelerometer output signals to be in digitalized form. Pulse counting accelerometers satisfy this need, since their pulse output can be supplied directly to computers. A schematic of a pulse counting accelerometer circuit can be seen in figure 11-9 (A), while the cutaway view is shown in figure 11-9 (B).

With velocity remaining constant, the brush spring holds the mass at null and the brush rests on the reset contact of the switch. As acceleration occurs, the tendency of the mass to remain at a constant velocity causes the spring to compress. In doing so, it allows the brush to move off the reset contact; and if acceleration is great enough, the brush will pass over the switch contacts for acceleration levels 1, 2, 3, and 4. These levels are determined by the stiffness of the spring.

As the brush passes over each contact (in a positive direction), an output pulse from each

13462

194

contact is coupled to one of four counters. This advances the counter one-half count. The accelerometer is so designed that as acceleration decreases and the mass tends to assume the new velocity, the counters will not advance the remaining half count until the brush once again touches the reset contact. With this type of pulse output, it is possible to record each time gravity forces have reached a predetermined level.

Applications

There are many types of accelerometers in use today; the examples given constitute only three of them. However, since the basic principle that a mass in motion tends to remain in motion and one at rest tends to remain at rest applies to all accelerometers, all of them can be considered similar.

Vertical reference accelerometers are used to measure either position or negative acceleration, while the counting accelerometer determines vertical movement in one direction only. Force balance accelerometers aid in determining an aircraft's present geographical position in relation to its previous geographical position. This is accomplished by computing the aircraft's acceleration in both the North-South and East-West directions. The aircraft's navigation system combines this information with other inputs to determine the distance the aircraft has traveled and the direction of travel from a previous position.

MAGNETIC COMPONENTS

A basic coverage of magnetism and magnetic properties and components is presented in Basic Electricity and in Basic Electronics. The discussion in the current chapter is devoted to some of the specific details and applications of primary interest to personnel involved in maintenance of avionic equipment which make use of these devices.

Both permanent magnets and electromagnets are employed in airborne electronic equipment. A few of the many specific uses of permanent magnets are in the focusing of CRT electron beams, in the rotors of electric generating devices, in variable reluctance pickoff devices, and in magnetrons. A few of the many specific applications of electromagnets are in relays, in CRT deflection systems, in rotating electrical devices, and in magnetic amplifiers.

The main distinction between the two basic types lies in the fact that electromagnets retain their magnetic properties only while the electrical energy is applied; the permanent magnet requires no electrical energy in order to retain its magnetic state.

AT.190

Figure 11-9.–Pulse counting accelerometer.

13463

FERRITE MATERIALS

Magnetic materials are those materials which, either as their natural condition or due to some external influence, possess magnetic properties. The term FERRITE is applied to that portion of the latter group which possesses specific useful characteristics. Ferrites are hard, brittle, crystalline materials produced from a mixture of powdered materials including iron oxides.

By altering the mixture, ferrites may be developed to exhibit a variety of magnetization characteristics. Some ferrites are well adapted for use at low frequencies (such as magnetic amplifier cores and memory cores in computers), but are not usable at high frequencies (especially those frequencies falling in the microwave region). Microwave ferrites will be discussed in a later section of this chapter; the current discussion is limited to those ferrites used in lower frequency ranges.

The basic theory of magnetization is presented in Basic Electronics. Although that discussion is concerned primarily with general magnetic materials, it is equally applicable to ferrites. As mentioned previously, ferrites are a special class of magnetic materials developed to exhibit special characteristics.

Ferrites are classified in accordance with the special characteristics they exhibit. These characteristics include the relative and specific B-H relationships, flux densities attainable, eddy current and hysteresis losses, residual losses, permeability, temperature coefficient, and magnetic retentivity. For practical usage, the ferrite material is selected on the basis of the values of these characteristics required in the particular application.

Table 11-1 illustrates some practical applications of ferrite materials at low frequencies, and lists the properties of each. In this table, Q is a figure of merit representing the energy ratio of useful conversion (into magnetic energy) to losses.

MAGNETIC AMPLIFIERS

Magnetic amplifiers, as the name implies, are amplifiers which operate through magnetic properties rather than electron tube principles. In aviation electronics applications, their major function is as a servomechanism control device. As an amplifier, this device permits the use of a small control signal to govern the operation of a much larger device requiring considerable power.

A typical magnetic amplifier consists of multiple windings on a common core. (See fig. 11-10.) Under static (no signal) conditions, the core is partially saturated by the flow of a d-c current in one of the windings (bias). An error signal (either a-c or d-c voltage) applied to a second (control) winding varies the degree of saturation, thus changing the permeability of the core. The changing permeability controls the flux cutting the third (load) winding, and permits the change in magnitude and instantaneous polarity of the voltage applied to the servomechanism to control the direction and speed of correction.

In closed loop servosystems, the magnetic amplifier has a fourth (reference) winding which applies the feedback signal to the system. This system improves circuit operation by decreasing the hunting effect and canceling the error input when actual operation of the load coincides with the desired operation.

Magnetic amplifiers used in airborne electronic equipment are of many different configurations, depending on specific application. The saturable current potential transformer is one type of magnetic amplifier.

Magnetic amplifiers may be broadly classified as belonging to the saturable reactor type or to the self-saturation type. These two types are discussed very briefly in the following paragraphs. If more details are desired a comprehensive discussion is available in a series of articles appearing in the DIGEST during 1963 and 1964. Reprints of this series are also available in booklet form.

Saturable Reactors

A magnetic amplifier is classed as a saturable reactor if the individual load currents are bidirectional, even though the load circuit may employ rectifiers to operate a d-c operated load.

The reactor core normally has a rectangular B-H loop. The no-signal flux is established by the d-c bias winding; the error signal is applied in series with this d-c to vary the degree of saturation. This combined signal and biasing ar-

Table 11-1. —Summary of ferrite applications.

Type of components	Typical frequency	Characteristics desired
LINEAR B-H CHARACTERISTICS:		
Filter inductors	100 kHz	High Q, precision, stability, low modulation.
IF transformers	465 kHz	High Q, stability, adjustability.
Antenna cores	1,000 kc to 15 mHz	Moderate Q, stability.
Wideband transformer	1,000 kc to 15 mHz	Reproducible transmission properties.
Adjustable inductors	Various	Adjustment range 20 percent.
Tuners	Various	Adjustment range greater than 10:1.
Miniature inductors	Various	Moderate Q, small size.
Loading coil	Voice	Stability, low modulation, low flux leakage.
NONLINEAR B-H, MEDIUM TO HIGH FLUX DENSITIES:		
Flyback transformers	15-100 kHz	Low losses, moderate size, retentivity, high Curie temperature.
Deflection yokes	Pulse	Same as above.
Miniature transformers	Pulse	Small size, easy mounting.
Carrier power transformers	Various	Low eddy current, high μ, high resistive impedance.
Supression heads	Various	Same as above.
Recording heads	Various	Very high μ, low eddy current, mechanical rigidity.
HIGH NONLINEAR, RECTANGULAR LOOP:		
Memory cores	Pulse	Two stable states, fast flux reversal, low eddy current.
Switching cores	Pulse	Fast flux reversal, high output.
Multiaperture cores	Pulse	Fast flux reversal, low eddy current.
Magnetic amplifiers	Various	High μ, up to saturation, almost horizontal B-H line above saturation.
MAGNETOSTRICTION AND OTHER PROPERTIES:		
Delay lines	Pulse, various	Low B's are acceptable, high μ at high frequencies.
Filters and oscillators	100 kHz	Same as above.
Temperature controls	Various	Sensitivity to temperature.
Transducers	20-30 kHz	High power outputs, mechanical strength.

AT.191

Figure 11-10.–Typical magnetic amplifier, simplified.

rangement controls the permeability of the core, and thus the inductive reactance of the a-c load winding. The inductive reactance of the a-c load winding, in turn, governs the power applied to the load. (See fig. 11-11.) Control of a d-c load requires the use of rectifiers in series with the load (not shown).

Self-Saturating Reactors

A magnetic amplifier is of the self-saturating type if the individual load currents are unidirectional, being gated on and off by rectifiers for some period less than one-half the a-c voltage cycle. The major difference in the construction of the self-saturating reactor (fig. 11-12) and the saturable reactor (fig. 11-11) is the addition of the rectifier in the load circuit and the reversal of the bias voltage. Differences in operation, however, are somewhat more extensive.

The self-saturating magnetic amplifier is limited in use to d-c loads, but is capable of a much higher gain. Instead of merely increasing or decreasing the flux, the self-saturating amplifier is capable of changing the flux from almost zero to nearly complete saturation.

INDICATORS

Many different types of indicators are used in airborne electronics equipment for numerous purposes. The indicators of greatest concern to the technician use the cathode-ray tube to furnish a visual display. Other important types of indicators include the various meters, dials, etc., used in test equipment, computers, communications equipment, electronic navigational aids, and radar applications.

CRT DISPLAYS

Basic discussions of the cathode-ray tube and its applications and associated circuitry appear throughout Basic Electronics and the present manual. Basic Electronics presents information on the CRT itself and its applications in oscilloscopes and synchroscopes, some of the major types of scans used in radar equipment, and the sawtooth generators which develop sweep voltages. The present manual presents discussions of many of the circuits used in CRT indicators and numerous actual applications of the CRT indicator in operational and test equipment. The cathode-ray tube indicator, therefore, is not discussed in detail at this point.

F3085466

OTHER INDICATOR TYPES

Indicators may be classified in many different ways. One method of classification is based on the affected sense. Technicians are concerned with two classes–visual and aural. Since aural indications are comparatively unreliable for accurate interpretation, their use is limited to rough analyses of loudness and intelligibility. This discussion, therefore, is limited to visual indicators.

Visual indicators are also classifiable by many systems. For this discussion, classification is based on the basic operating principle of the device. A listing of the types of indicators would include the following classes, as well as many others:

1. Lights.
2. Rotary counters.
3. Linear displacement mechanisms.
4. Direct angular displacement devices.
5. Remote angular displacement devices.

Lights

Indicator lights are commonly used to indicate the operating status of circuits or equipment. Many items of test equipment use lights to indicate that power is applied to the equipment. Some use additional lights to denote whether the equipment is in full operation or on standby. Aircraft consoles use trouble lights to designate malfunctioning circuits or components. Computers use lights as readout devices for some purposes.

Indicator lights may be coded as to color, sequence, or position. They may also be controllable as to intensity. They may be stationary or rotating.

Rotary Counters

Rotary counters, as used in this discussion, are similar to the odometer (mileage indicator) on automobiles. In avionics applications, their most common usages include the following:

1. Distance and/or direction indicators in navigation systems.
2. Computer readout devices.
3. Frequency channel indicators in communications equipment.
4. Elapsed time indicators.
5. Specific occurrence counters.

Direct Angular Displacement

Direct angular displacement devices are also usually analog devices. This class of indicators includes the conventional current-operated meters, altimeters, compasses, etc., as well as the dials used to indicate switch positions, etc.

Linear Displacement

Linear displacement mechanisms, although not commonly used as final indications in avionics work, are frequently used as input devices. These devices are usually analog devices, rather than direct-reading indicators. The linear displacement of a moving part of the device is proportional to some quantity to be measured. The final indicating device is usually driven through a converter and some type of servosystem.

Remote Angular Displacement

Remote angular displacement indicating devices are those which are driven through a synchro system which is, in turn, driven by a direct angular displacement device.

Multipurpose Indicators

The avionic installations of modern aircraft have become extremely complex. Space and weight factors prohibit the use of single-purpose devices to provide each required indication. Multipurpose instruments are becoming increasingly common in aircraft, and may be broadly classified into three types.

One type of multipurpose indicator uses a single indicating mechanism for all indications. The circuit connections are switched so that any one of the various quantities may be indicated. This type is used in multimeters, radar systems, navigation equipment, etc. The quantities to be indicated must be converted into the same form in the associated circuitry prior to application to the instrument.

A second type of multipurpose instrument can provide several indications simultaneously on a single instrument. This type uses angular

00042467

displacement, with all pointers using a common axis of rotation. Each pointer is driven by its own mechanism through concentric shafts.

The third type of multipurpose instrument consists of a completely separate mechanism for each indication, with all mechanisms enclosed within a single housing. The individual mechanisms may be of the same or of different basic types. Two actual instruments falling in this class are the bearing-distance-heading indicator (BDHI) and the horizontal situation indicators (HSI) discussed in the following paragraphs.

In the horizontal situation indicator (HSI) the lubber line and aircraft symbol (fig. 11-13) are fixed in position and are used as basic references for all angular indications. The command heading marker may be positioned manually by the heading set knob, or it may be automatically positioned during computer navigation mode of operation. Indicator lights behind the various mode words are used to indicate the mode of operation of the navigation system, and to designate which equipment is selected for positional and bearing reference.

The compass card, bearing pointer, command heading marker, and course pointer revolve around a common axis. The course deviation bar revolves around a central point; movement may thus appear as both linear and angular displacement.

The to-from pointer is a two-position indicator used with TACAN, as described in chapter 17 of this manual. The course set knob is used to position the course pointer.

The instrument also includes counters to indicate course and distance to a TACAN station or to a selected point. Bearing, without distance, may also be indicated to a navigation station or any UHF station under proper operating mode selections.

MICROWAVE COMPONENTS

As discussed in chapter 9 of this manual, the effects of stray and distributed capacitance and inductance increase as the operating frequency is raised. Chapter 10, in the discussion of transmission lines, presents an example of how the distributed properties are used. The

UNIT II - USE OF DRAWING INSTRUMENTS

Protractor Lesson 5

OBJECTIVE: To learn to use a protractor.

RELATED INFORMATION:

A protractor is used to measure angles (Fig. 1). The intersection of the two hair lines at O is placed at the origin of the angle, with the horizontal line along one of the given sides. The angle is then read along the scale. Angles from 0° to 180° can be read directly, either from right to left or from left to right.

PROTRACTOR

FIG. 1

The smallest division represents one half degree. In the event that a problem requires a measurement between a half degree and a full degree, it must be estimated.

ASSIGNMENT:

Construct the polygon shown below, drawing the horizontal line AK of indefinite length about 1 inch above the bottom of your drawing paper. From A draw and measure AB. Proceed in the same way for the remaining sides. Use your protractor to obtain the angles.

present discussion shows how the properties are used in components developed for use in microwave applications. It also includes a brief discussion of the ferrites used in microwave systems.

WAVEGUIDES

Basically, the waveguide is a special class of transmission line. The development of the waveguide from the two-wire transmission line (which was discussed in chapter 10 of this manual) is illustrated in figure 11-14. In a two-wire line, a quarter-wave section at the signal frequency presents a highly resistive impedance. Thus, a quarter-wave shorted stub may be used as an efficient insulator. If the stub offers adequate mechanical strength, it may be used to support the line while insulating it.

A rigid quarter-wave stub connected between the leads of a two-wire open transmission line (as shown in (A) of fig. 11-14) provides a starting point from which to discuss the development of a waveguide. In this type transmission line, efficient operation is limited to a single frequency. For all other frequencies, the insulating properties of the stub are decreased. A given stub represents a quarter wavelength at only one frequency (usually called the resonant frequency). At signal frequencies higher than resonance, the stub appears longer than a quarter wavelength, and presents an inductive impedance. At frequencies below resonance, the stub appears shorter than a quarter wavelength and offers a capacitive impedance. The greater the difference between the signal frequency and the resonant frequency of the stub, the smaller the total impedance offered by the stub. Since the stub normally has a very high Q, the effective useful range of frequencies is critical.

A metallic quarter-wave stub insulator may be placed at any point along a two-wire line. Use of several such stubs placed at convenient points along the line (as shown in (B)) improves the mechanical support of the line. Whether the stubs are used to support from above or below the line makes no difference.

If the stubs are connected together, the conductivity of the line is improved. Figure 11-14 (C) shows adjacent stubs connected by a switch. When the switch is open, each stub is excited

AT.195

Figure 11-14.–Development of a waveguide.

13469

separately by the signal in the main line. Standing waves are present on the line. Stub No. 1 is excited first, No. 2 at some time later. When the switch is closed, however, the No. 2 stub is excited partially by the signal on the main line, and partially by the No. 1 stub (through the switch). If the switch is connected to corresponding points on the two stubs, the relative phase relationship of the signal at the connections is the same. Thus, the No. 2 stub requires less excitation energy; the parallel paths offer less resistance (and therefore less copper loss) and energy transfer is more efficient.

Increasing the number of stubs increases the operating efficiency. A hollow rectangular tube effectively represents a parallel line with an infinite number of stubs. Given the proper dimensions, this device becomes a highly efficient transmission line. In the waveguide shown in figure 11-14 (D), successive "stubs" are in physical and electrical contacts with each other. This effectively connects corresponding points together, and automatically provides for proper phasing.

Dimensions

As discussed previously, the stub length in open two-wire transmission lines is quite critical. In waveguides, however, the dimensions are somewhat less restricted. Figure 11-15 indicates the main dimensions of rectangular waveguides.

The waveguide shown in figure 11-15 is operating at a frequency which is the approximate minimum usable frequency. At this frequency, the waveguide is effectively a two-wire transmission line with an infinite number of shorted stubs (indicated by dashed lines in the figure). At any signal frequency higher than the one illustrated, the width of the two leads of the effective line is increased, and the remaining portion of the stub then represents a quarter wavelength. At frequencies lower than the one illustrated, however, the stubs are less than a quarter wave and the leads are not adequately insulated. Thus it may be assumed that the (a) dimension of the waveguide is not critical, except that the signal must be at least a certain minimum frequency.

In open transmission lines, the spacing of the lines is critical only with respect to voltage breakdown. If the wires are placed too close together, arcing can occur, and energy losses become excessive. The same principle applies to the (b) dimensions of the waveguide.

AT.196

Figure 11-15.–Dimensions in rectangular waveguides.

The main limitation on the length of either the open line or the waveguide is the energy losses incurred by the signal in transit through the device from one end to the other.

The frequency at which the quarter-wave stub sections appear to meet and cease to exist is called the CUTOFF FREQUENCY, and the corresponding wavelength is called the CUTOFF WAVELENGTH. Thus the analogy provides a basis for the formula $\lambda_{co} = 2a$ (given in Basic Electronics). In this formula, λ_{co} is the wavelength at the cutoff frequency of the waveguide, and (a) is the wide dimension as indicated in figure 11-15. In practical waveguides, the (b) dimension is normally between 0.2 and 0.5 wavelength at the cutoff frequency.

Energy in Waveguides

Energy is transferred within the waveguide by electromagnetic fields; currents and voltages merely aid in establishing these fields. In understanding the operation of waveguides, it is important to know when a good current path is required and where the voltage must be high. It is also important to know where strong fields will exist and to understand the composition of the fields. It is normally by means of fields that energy is introduced into or removed from the

13470

waveguide. The operation of the waveguide involves two field components–the electric field and the magnetic field.

ELECTRIC FIELD.–As discussed in Basic Electricity, the existence of an electric field indicates that a difference of potential exists between two points. An excited transmission line has a standing wave of voltage along its path; part of the line is positive, part is negative. An instantaneous field is set up between the wires. The standing wave, and therefore the electric field, varies in magnitude (intensity) progressively along the line. Since the exciting voltage varies at a sine wave rate, the electric field also varies sinusoidally.

The electric field, as it exists in a waveguide, is shown in figure 11-16 (A). This is an instantaneous representation of the field at its peak. Over a period of time (during each cycle), the field decreases to zero, reverses polarity and builds up to another maximum, decreases to zero, then reverses and expands again. Successive zero points occur at half-wave intervals along the length of the line; successive maxima, alternating in polarity, also occur at half-wave intervals.

NOTE: In illustrating the direction of the fields, standard practice is to use dots (·) and crosses (x). The (·) inducates that the direction of the field is toward the observer; the (x) indicates that the field is away from the observer.

Note that the lines of force which make up the electric field (called the E-lines) exist between the (b) dimension walls, and are perpendicular to the wide (a) dimension walls. Also note that the field has maximum intensity halfway between the (b) dimension walls, decreasing toward zero as it nears the wall. (The importance of this characteristic is covered later in this discussion.)

MAGNETIC FIELD.–Any expanding and collapsing electric field creates an alternating magnetic field. A visual representation of the sinusoidal magnetic field at an instantaneous maximum point is shown in figure 11-16 (B). Note that the field forms closed loops approximately half a wavelength long, with successive loops reversed in polarity. Note also that the magnetic lines (called H-lines) are parallel to the walls of the waveguides.

The magnetic field is strongest at the edges of the waveguide and weakest at the center of each loop (where the standing wave of current is zero at all times).

COMPOSITE FIELD.–Electromagnetic waves are made up of electric and magnetic field components. Energy travels down the waveguide in the form of wavefronts.

As the wavefront progresses down a waveguide, it interacts with a wavefront reflected from the other end. This interaction results in standing waves (similar to the standing waves of current and voltage in transmission lines). It is in these standing waves that the energy exists within the waveguide. Figure 11-16 (C) illustrates the composite electromagnetic standing waves in a section of waveguide.

In the figure, note that the electric and magnetic components of the composite field are oriented mutually perpendicular to each other and to the direction of propagation. Also note that the points of maximum electric and magnetic field intensity coincide, as do the points of minimum field strength. Propagation of energy in waveguides differs in some respects from that in free space.

In free-space propagation, the transmitted wave expands in an everwidening circle. In waveguides, it is confined within the conductive walls, and no electromagnetic field exists outside the waveguide. Instead, as the wave travels down the guide, it strikes the walls at an angle and is reflected at an equal angle. If energy propagation is to be sustained within the waveguide, two major "boundary" conditions must be fulfilled.

BOUNDARY CONDITIONS.–The first boundary condition that must be met is that there must be no component of the electric field tangent to the walls of the waveguide. An electric field is equivalent to a voltage; when impressed across a perfect conductor (the walls of a waveguide), it is decreased effectively to zero. Thus the parallel component of the E-field diminishes to zero as it approaches the walls. The remaining component of the E-field is perpendicular to the walls in the (a) dimension.

The second boundary condition concerns the magnetic field. No component of the magnetic field can exist perpendicular to the inner surface of the waveguides. Since the electric and magnetic components of the composite field are mutually perpendicular, satisfaction of one boundary condition usually guarantees satisfaction of the other also.

13471

AT.197

Figure 11-16.–Fields in waveguides. (A) Electric; (B) magnetic; (C) composite electromagnetic.

13472

Circular Waveguides

Waveguides have been developed which have a circular cross section as well as those having a rectangular cross section. Although in less common usage than rectangular, circular waveguides have characteristics which make them particularly useful in some applications. In general, the development of the circular waveguide may be explained in the same manner as that of the rectangular.

The two conductors represented by the dashed lines in figure 11-17 are assumed to be part of the waveguide wall. The remaining part of the wall represents the quarter-wave stub section which act as the insulators.

The cutoff wavelength of the circular waveguide is 1.71 times the diameter of the guide. The diameter must be 1.17 (2/1.71) times the (a) dimension of a rectangular waveguide having the same cutoff frequency.

Modes in Waveguides

As mentioned previously, at frequencies higher than cutoff, the wide dimension of the waveguide becomes increasingly greater than a half wavelength. At a frequency twice that of cutoff, this dimension is a full wavelength, with each stub then representing a half-wave section. If the waveguide and its fields are to fulfill the boundary conditions required for propagation, the field configuration must be quite different from that previously indicated. In other words, the waveguide must assume a different mode of operation.

AT.198

Figure 11-17.–Circular waveguide.

The normal configuration of the electromagnetic field in a given waveguide is called the DOMINANT MODE OF OPERATION of that waveguide. Other modes are also possible in any waveguide, and some of these modes are used in radar applications.

Any field configuration can be classed as either a TRANSVERSE ELECTRIC MODE or as a TRANSVERSE MAGNETIC MODE (abbreviated TE or TM, respectively). In a TE mode, all parts of the electric field are transverse (perpendicular to the length of the waveguide) and no E-lines are sustained parallel to the direction of propagation. In a TM mode, the plane of the H-field is transverse and no H-lines are parallel to the direction of propagation.

A wavefront in free space is a TEM mode, since both fields are perpendicular to the direction of propagation. Due to the boundary conditions, however, this mode cannot exist in a waveguide. Under any set of operating conditions, one field in any waveguide will be predominantly transverse–this field determines the basic classification of the mode as TE or TM. To complete the description of the field pattern, two subscript numbers are used following the TE or TM.

In rectangular waveguides, the field is described in relation to the wide and narrow dimensions. The first subscript indicates the number of half-wave patterns of the transverse field across the wide dimension. The second subscript indicates the number of half-wave patterns of the transverse field across the narrow dimension. Both measurements are made across the center of the cross section.

In circular waveguides, the field is described in relation to the circumference and diameter. The first subscript indicates the number of full-wave patterns of the transverse field around the circumference of the waveguide. The second subscript indicates the half-wave patterns occurring across the diameter.

Figure 11-18 illustrates several modes which occur in waveguide operation. The dominant mode for rectangular waveguides is shown in (C), and the dominant mode for circular waveguides is shown in (F).

13473

AT.199

Figure 11-18.–Modes and field configurations in waveguides.

Note in (D) and (E) that the electric field is axial; therefore the magnetic field is transverse and the modes are designated TM.

Excitation of Waveguides

As with any transmission line, the waveguide must be properly excited in order to carry the energy from one point to another. Waveguides, however, do not have the two convenient connection points possessed by the conventional RF line. In waveguides, the energy is in the form of an electromagnetic wave; therefore the excitation device must cause these fields to be created within the guide. Excitation may be in either of three principal forms–electric fields, magnetic fields, or electromagnetic fields.

ELECTRIC FIELD.–Inserting a small probe or antenna into a waveguide and applying an RF signal causes current to flow in the probe. This current sets up an electrostatic field; E-lines detach themselves from the probe and propagate in the waveguide. The propagating E-lines establish corresponding H-lines and result in the formation of a composite electromagnetic field within the waveguide. If the probe is positioned

13474

in the proper location and supplied the proper signal for a specific waveguide mode, a field having considerable intensity may be established and sustained.

Figure 11-19 (A) illustrates the excitation of a waveguide by means of an electric field.

The best place to locate the probe is in the center of the wide dimension, parallel to the narrow dimension, and one-quarter wavelength away from the shorted end of the guide, as shown (the field is strongest at the quarter-wave point). This is the point of maximum coupling between the probe and the field.

The probe will work equally well at any point where E-lines exist with maximum intensity (for example, a three-quarter wavelength distance from the shorted end).

Usually the probe is fed with a coaxial cable. This cable is kept short to derive greatest benefit from the waveguide. Impedance matching between the cable and the waveguide is accomplished by varying the distance of the probe from the end of the waveguide (by moving the shorted end) or by varying the length of the probe. Any mismatch will cause unwanted reflections within the waveguide.

The degree of excitation can be reduced by reducing the length of the probe, moving it out from the center of the E-field, or shielding it. Where it will be necessary to vary the degree of excitation frequently, the probe is made retractable, and the end of the waveguide is fitted with a movable plunger.

In pulse-modulated radar systems there are wide sidebands on both sides of the carrier. In order that a probe feed system does not discriminate too sharply against frequencies which vary from the carrier frequencies, WIDEBAND probes are often used. A wideband probe is large in diameter and is conical or doorknob in shape. A conical probe is capable of handling moderate amounts of power, but for the high power sets, doorknob probes are used. The same types of probes are used to take energy out of waveguides and deliver it to coaxial cables.

MAGNETIC FIELD.–Another way of exciting a waveguide is by setting up a magnetic H-field in the waveguide. This can be accomplished by placing a small loop which carries a high current in the waveguide. A magnetic field builds up and expands until it fills the space within the waveguide. If the frequency of the current is correct, energy will be transferred from the loop to the waveguide. A loop for transferring energy into a guide is shown in figure 11-19 (B). Notice that the loop is fed by a coaxial cable. The location of the loop for optimum coupling to the guide is at the place where the magnetic field, which is to be set up, is of greatest strength.

When less coupling is desired, the loop may be rotated or repositioned until it encircles a smaller number of lines of force.

Figure 11-19.–Exciting a waveguide.

AT.200

13475PT1

When an excitation loop is used in radar equipment, its proper location is often predetermined and fixed either during construction or final tuning at the factory. In test or laboratory equipment, the loop is often made adjustable.

When a loop is introduced in a guide at a point where an H-field is present, a current will be induced in the loop itself. Thus, the loop may take energy out of the waveguide as well as put energy into it.

ELECTROMAGNETIC FIELD.—It might seem that a good way to excite the waveguide or to couple energy out of it is simply to leave the end open. However, this is not the case; when energy leaves a guide, fields exist around the end which result in mismatch. In other words, reflections and standing waves would result if the end were left open. Thus, simply leaving the end open is not an efficient way of letting energy out of the waveguide.

In order for energy to move smoothly into or out of a guide, the opening of the guide may be flared like a funnel. This makes the guide similar to a V-type antenna. This method, shown in (C) is called a horn and in effect eliminates reflection by matching the impedance of free space to the impedance of the waveguide. When the mouth of the horn is exposed to electromagnetic fields, they enter and are gradually shaped to fit the waveguide. The horn is directional in characteristic. It sends or receives the greatest amount of energy in front of the opening.

Another method for either putting energy into or removing it from waveguides is through slots or openings. This method is sometimes used when very loose coupling is desired. In this method (fig. 11-19 (D)), energy enters the guide through a small aperture. Any device which will generate an E-field may be placed near the aperture, and the E-field will expand into the waveguide. A single wire is shown; on it, E-lines are set up parallel to the wire due to the voltage difference between parts of the wire. The E-lines expand first across the aperture, then across the interior of the waveguide. If the frequency is correct and the size of the aperture properly proportioned, energy will be transferred to the waveguide with a minimum of reflections.

EXTRACTION OF ENERGY.—In waveguides, as with many other electrical networks, reciprocity exists in the excitation system. Reciprocity means that energy may be either introduced into the waveguide or removed from the waveguide, using the same coupling devices and methods, with the same efficiency of transfer.

RESONANT CAVITIES

By the simple expedient of closing the ends of a waveguide to form an enclosure, a cavity is formed. If this cavity is then excited in a proper manner by the proper frequency, it will resonate. The resonant frequency of the cavity is determined by the dimensions, which are somewhat more critical than those of a waveguide.

In order to resonate, the cavity makes use of the distributed inductance and capacitance of the enclosing box. This limits the practical use of resonant cavities to microwave frequencies. However, at microwave frequencies, resonant cavities normally possess value of Q considerably in excess of any value obtainable with lumped components at lower frequencies.

Fields in Resonant Cavities

As in the waveguide, operation of the resonant cavity is best described in terms of the fields rather than in terms of currents and voltages. Cavities may have various physical shapes. A chamber enclosed within conductive walls may resonate at any of several frequencies and thus produce a number of field configurations, depending on the size and shape of the chamber. As in waveguides, these field configurations are called modes. Figure 11-20 illustrates several shapes of cavities and the dominant mode of each.

Of the types shown in the figure, the cylindrical type cavity (B) is useful in wavemeters or other frequency measuring devices. The cylindrical ring (E) and doughnut (D) are used in many microwave oscillators as the frequency-determining element. The waveguide section (F) is used in some radar systems as a mixing chamber for combining signals from two sources. The cube (A) is a special type of waveguide section. The sphere (C), although not in common usage, may be used for mixing multiple inputs, for extracting multiple outputs, for changing the mode of operation, or for impedance matching.

Note that in each type cavity shown, the voltage is represented by E-lines between the top and

13476

AT.201

Figure 11-20.–Fields in resonant cavities.

bottom of the cavity. The current, due to skin effect, flows in a thin layer on the surface of the cavity. The H-field is strong where the current is high; the strongest H-field is at the vertical walls of the cavity, and diminishes toward the center where the current is zero. This characteristic results from the presence of standing waves, similar to the action on a quarter-wave section of transmission line or waveguide. The E-field is maximum at the center and decreases to zero at the edge where the vertical wall is a short circuit to the voltage.

The modes in a cavity are identified by the same numbering system that is used with waveguides, except that a third subscript is used to indicate the number of patterns of the transverse field along the axis of the cavity (perpendicular to the transverse field). For example, the cylindrical cavity shown in (B) is a form of circular waveguide. The axis is the center of the circle. The transverse field is the magnetic field; therefore, it is TM (transverse magnetic). Around the circumference there is a constant magnetic field. (The H-lines are parallel to the circumference.) Therefore, the first subscript is 0. The distance across the diameter is one-half wave; thus the second subscript is 1. Through the center, along the axis, the H-field strength is a constant zero; this makes the third subscript 0. The complete description of the mode is $TM_{0,1,0}$.

When a section of waveguide is closed on both ends in the form of a rectangular cavity, shown in (F) of figure 11-20, standing waves are set up and resonance occurs. The simple mode in this cavity is the same as the dominant mode of a rectangular waveguide; that is, it is $TE_{1,0}$. The third subscript of the mode, which is determined by a plane perpendicular to the E-field, is 1. Thus the complete description of the simple mode in the rectangular cavity is $TE_{1,0,1}$ (transverse electric).

Exciting the Cavity

A cavity resonator may be excited in any of three predominant methods. These methods are illustrated in figure 11-21.

The first method (A) is by inserting a probe into the cavity. The voltage applied to the probe sets up an E-field with the E-lines parallel to the probe. As the E-field expands, it in turn sets up an H-field. These fields expand and collapse; the wavefronts travel through the cavity and are reflected from the end. If the physical dimensions are correct, these wavefronts will return at the proper time to reinforce the original fields and produce standing waves. Due to

AT.202

Figure 11-21.–Exciting the cavity.

the high Q of the cavity, these oscillations will sustain themselves for an appreciable time, thus requiring only occasional excitation.

Another method (B) uses a magnetic loop. The loop is placed in a region where the magnetic field will be located. The currents in the loop set up an H-field within the cavity. The expanding and collapsing of the fields and the reflection of the wavefronts combine to maintain each other (if the size of the cavity is correct).

Either of the above methods may also be used to remove energy from the cavity.

A third method (C) is used with a cylindrical ring type cavity. The energy is placed into the cavity by clouds of electrons, which are virtually "shot" through the holes in the center of a perforated plate. As each cloud passes through, it creates a disturbance in the space inside the cavity until a field is set up. It may be said that the cloud of electrons produces a voltage difference between the perforated plates, and thus sets up an E-field.

Tuning the Cavity

Three methods for adjusting the resonant frequency in a cavity are shown in figure 11-22. One method uses a cylindrical cavity with an adjustable disk. When a $TE_{0,1,1}$ mode is used, the size of the cylinder may be changed along the axis to change the resonant frequency. The smaller the volume of the cavity, the higher the resonant frequency. The movement of the disk may be calibrated in terms of frequency. Usually in the case of high frequency equipment, a micrometer adjustment is used to change the position of the disk.

A second method of tuning the cavity employs threaded plugs which are inserted in the side of the cavity. The plug reduces the length of the magnetic field in the cavity in a manner similar to reducing the inductance of the tuned circuit.

UNIT III - DRAWING GEOMETRIC CONSTRUCTIONS

Bisecting a Line — Lesson 1

OBJECTIVE: To learn to bisect a line using ruler and compass.

RELATED INFORMATION:

In almost all machine drawings some form of geometric construction is required to permit the draftsman to prepare his drawing quickly and accurately. A good understanding of geometric constructions is very important because of their practical application in drafting. Several of the most commonly used geometric constructions will be discussed in this unit, along with their applications.

Bisecting a straight line consists of finding the exact center of the line without measuring its length.

To bisect the given line AB, place the needle point of your compass at point A and open the compass to any convenient radius of more than one-half the length of the line. Strike the arc as shown. With the same radius, set the needle point of the compass on point B and strike an arc intersecting the first arc at two points. Draw a straight line with a straightedge through the points where the arcs intersect. The line drawn will bisect the line AB.

FIG. 1

Application:

To locate a hole in the center of the shaft shown in Fig. 2, proceed as stated above. Draw both views. Scale the dimensions needed from the drawing shown.

FIG. 2

The deeper the plug extends into the cavity, the higher the frequency.

In the third method, the interior of the cavity, which is part of the interior of a vacuum tube, is sealed and evacuated. In this method a frequency change occurs whenever the top and the bottom of the cavity are moved away from (or toward) each other. This is accomplished by turning a screw which passes through two bowed struts. As the distance varies, the volume and the capacitance between the top and bottom of the cavity are changed. As the change in capacitance is the chief result of the change in the distance between the plates, the resonant frequency is proportional to the distance from the top to the bottom.

Another way of changing the frequency (not shown) is by changing the method of exciting the circuit. This can be done by making the exciting element either capacitive or inductive. (This can occur either accidentally due to improperly tuned circuits or deliberately as a means of tuning the cavity.)

MAGNETRONS

A magnetron is used as the transmitting tube in most pulsed transmitters operating at frequencies above 1,000 MHz. The fact that transit time has little influence on the magnetron, whereas it is a limiting factor in the operation of conventional tubes, makes this type tube desirable for microwave pulsed operation. Several other types of oscillators have been developed to compete with magnetrons as radar high power oscillators. In addition, there are some velocity modulated tubes (such as the klystron) which operate in the radar range and are capable of greater power output than the triodes. Klystrons are discussed later in this chapter.

The magnetron, which is a self-excited oscillator, possesses rather poor frequency stability when compared with the most stable lower frequency oscillators (electron coupled or crystal controlled). However, the overall system does provide adequate stability when AFC is used with the local oscillator.

As explained in Basic Electronics, the magnetron is a type of diode having an axial magnetic field perpendicular to the electric field between its cathode and anode. The magnetic field could be produced by an electromagnet but is usually provided by a permanent magnet.

The tube consists of a cylindrical plate, with a cathode positioned coaxially inside it. The tuned circuits in which the oscillations take place are resonant cavities within the plate structure.

Theory of Operation

The theory of operation of a magnetron is based on the effects of electric and magnetic fields upon electrons moving within the fields. These effects are as follows:

1. Within an electric field, a moving electron is subjected to a force proportional to the strength of the field and in a direction opposite to it.
2. Within a magnetic field, the force exerted is in a direction mutually perpendicular to both the field and the direction of electron movement.
3. Within mutually perpendicular electric and magnetic fields, the path of the electrons is determined initially by the velocity of the electron, and is then modified by the individual and combined effects of the two fields.

The fundamentals of magnetron action, using a permanent magnet and a pulsed d-c electrostatic field, are explained in Basic Electronics, NavPers 10087-B. An important conclusion, which results from the fundamental observations found in Basic Electronics, is summarized in the following paragraph.

For a fixed applied d-c potential, the radius of curvature of the electron path is determined by the strength of the magnetic field. By increasing the d-c potential, however, the velocity of the electron is increased and the magnetic field has a greater effect on the electron path, decreasing its radius. Thus the path of the electron can be altered by changing the strength of either the electric field or the magnetic field. The strength of these fields is critical, because they determine the path of the electrons, thus determining the efficiency of the tube.

GENERATION OF A. C.–In order to produce an a-c voltage in a magnetron, a split (or segmented) anode and a strong axial H-field are required; a high d-c potential is then applied to all anode segments. (The anode must be split into an even number of segments, and the cathode preheated to emit electrons.) As soon as the d-c voltage and the magnetic fields are applied, oscillations build up and the segments become

alternately positive and negative. The a-c power is generated by transferring a portion of the d-c power (consumed in the circuit) into a-c energy (in the oscillations) as described below.

The applied d-c voltage accelerates the electron, which starts to move toward the anode segment having the higher positive potential at that instant. The energy of the applied d. c. is thus transferred to the electron as kinetic energy. Strong magnetic fields force the electron to follow a sharply bent spiral path. As the field reverses, the electron is slowed down (due to a decrease in the accelerating force of the d-c field) and transfers some of its kinetic energy to the a-c field of oscillation. The electron may spiral several times before reaching the anode, thus giving up most of its energy to the alternating field. (See fig. 11-23.)

In this magnetron, the frequency of oscillation is determined by the transit time of the electrons, and is quite unstable. Electrons arriving at the anode segments a little early tend to increase the frequency, while those arriving late tend to decrease it. In order to provide better stability, resonant circuits are introduced between adjacent anode segments, or between each anode segment and the cathode. The frequency of oscillation is then determined by the resonant frequency of these circuits. Since the stability of the circuit can be improved by using a higher Q resonant circuit, the use of resonant cavities is standard at those frequencies high enough to make this practical.

AT.204

Figure 11-23.–Split anode magnetron.

The RF fields in the cavities may or may not be in phase. The phase relationship is determined mainly by the applied voltage and the strength of the magnetic field, but some improvement in the phasing may be realized due to the coupling between the cavities. The desired coupling may be obtained by connecting selected segments together. This procedure is known as STRAPPING, and is covered in more detail in a later discussion.

The multicavity magnetron requires an even number of anode sections (usually eight or more) situated around a cylindrical chamber (called the INTERACTION SPACE) with the cathode coaxially centered inside it. A resonant cavity is located between each pair of anode segments, and may be connected to the interaction space by a narrow slot. (See fig. 11-24.)

The body of the magnetron and the anodes are at d-c ground potential, and a highly negative d-c potential is applied to the cathode. The resonant frequency is determined by the physical dimensions of the cavities. Due to the oscillations, high frequency potentials are imparted to the anode segments.

If each cavity is at a 180° phase relation with its neighbors, adjacent anode segments have opposite polarities at any given time. An oscillating E-field exists between each pair of segments in the path of the electrons. Strength of the magnetic field is relatively fixed; therefore the voltage applied to the cathode must be adjusted so that the majority of the electrons move against these oscillating fields and surrender most of their energy to the RF field, thus helping to sustain oscillation.

ELECTRON SPACE CLOUD.–Electrons within the interaction space do not travel individually, nor are they evenly spaced. Rather, they tend to gather into spoke-shaped clouds. In figure 11-24 (A), the space charge is shown as it would exist in a magnetron that is not oscillating (due to the lack of a d-c potential). In (B), the application of a d-c voltage sets up the d-c electric field as shown. The arrows indicate the direction of the field (positive to negative). It must be remembered that electrons will be accelerated so that they move in a direction opposite to that of the field.

With the establishment of the d-c field, the magnetron is shocked into oscillation, and RF fields are established. These RF fields set up

13480

AT.205

Figure 11-24.–Action of space cloud.

alternating polarities on adjacent anode segments. The alternating fields aid or oppose the d-c fields, and tend to accelerate or retard electrons in the space cloud.

Electrons being accelerated due to the addition of the two fields (such as electron "a" in (C) of figure 11-24) tend to absorb energy from the RF field. Due to their high velocity, the magnetic field has greater effect upon them, decreasing the radius of curvature and causing them to return to the cathode. They strike the cathode with high velocity, cause secondary emission, and give up their kinetic energy to the cathode in the form of heat. This is known as cathode back-heating. (Back-heating is often great enough to require a decrease or even removal of filament voltage from the magnetron as its cathode current nears its normal operating value.)

On the other hand, those electrons being retarded (electron "b" in fig. 11-24 (C)) due to opposing fields have their velocities decreased and impart energy to the RF field. Due to the decreased velocity, the radius of curvature is increased and the electron paths terminate at the anode. Sorting of electrons in the space charge tends to create spokes in the electron cloud. The spokes rotate in synchronism with

OSDSI 19481

the RF fields and the space cloud. Loss of sync between the clouds and the RF field tends to kill oscillation. The applied potential and the strength of the magnetic field are fairly critical, since they determine the intial velocity of the electron and vary radius of curvature during transit, respectively.

The spokes are rather narrow, with sharply defined boundaries–the result of focusing by the RF field. In (D), electrons traveling in advance of the spoke "a" are in an area where the radial components of the d-c and RF fields oppose. The velocity of the electron is decreased and the radius of curvature is increased, allowing the spoke to catch up and collect the electron. Those electrons which lag the spoke "b" are in an area of aiding fields. Their velocity is increased, the radius of curvature is decreased, and the electron catches up with the spoke and is captured. Thus, capturing of electrons tends to focus the electrons into tight spokes, and keeps the edges sharply defined.

As the spokes of the electron cloud pass an anode segment, electrons are repelled from that segment, traveling around the cavity on either side to other segments. This action creates a positive charge on the segment being passed by the cloud. As the cloud rotates to the next segment, it encounters a maximum negative polarity (due to the electrons repelled from the previous segment). It again displaces electrons as previously, causing a polarity reversal. This displacement current is the principal current of the RF oscillation. If the alternation of RF field and the rotation of the space cloud are properly synchronized, the electrons reaching the anode from the interaction space have a 90° phase relationship and do not contribute to the oscillation. Electrons passing the gap (cavity) give up part of their energy to the RF fields, sustaining oscillation.

By varying the magnetic field strength or the d-c voltage applied to the cathode, it would be possible to "kick" the anodes slightly early or slightly late, thus varying the resonant frequency. However, there is a very narrow range through which the frequency can be varied in this manner, and the magnitude of oscillation decreases very rapidly with any change of sync. Therefore, this method is not in common use.

Modes of Operation

There are various modes of a magnetron, and they are identified by the number n, which specifies the number of cycles of variation of the field quantities that occur around the circumference of a circle surrounding the cathode. For each mode of oscillation of a magnetron, like those of other cavity resonators, there is a particular pattern of field variations. In the zero mode, the fields do not enter the anode cavities and the frequency of the mode is not controlled by the cavities; thus this is an undesirable mode of operation. With the exception of the π mode, all modes are degenerative. Degenerative modes are in reality a combination of two or more modes having the same resonant frequency. In the π mode of operation, adjacent anode segments are exactly 180° (one-half cycle, or π radians) apart in phasing.

These degenerative modes are caused by very close coupling between resonators having the same frequency, allowing the mutual inductance to either add or substract from the natural inductances of the cavities.

Since a slight variation may cause a shift from one of these modes of operation to another with a resultant change in output frequency, these modes are highly undesirable. Since the π mode of operation is not degenerative, it is the preferred mode of operation.

In order to insure operation in the π mode, the procedure known as STRAPPING is used. Since in the π mode of operation adjacent segments must be operating with a 180° phase relation, then alternate segments should be in phase. In order to guarantee this in-phase condition, alternate segments are connected as shown in figure 11-25 (A).

While operating in the π mode, there is no current flow through the straps, so there is a negligible inductive effect on the cavities. On the other hand, there is a very high electric field between each strap and the anode segment to which it is not connected. This adds an effective capacitance to the associated cavity, lowering its frequency. If the adjacent segments are not phased 180° apart, the magnetron tries to oscillate in an undesirable mode; the straps are then connected to points of unequal potential, and current flows in the straps. This current makes

each strap appear as an effective inductance in parallel with the cavity, increasing the frequency of this undesired mode and giving better mode separation. The potential difference between the strap and the segment decreases, presenting a lower effective capacitance to the cavity and increasing the frequency of the undersired mode even more.

NOTE: Some magnetrons make use of double ring strapping as illustrated in figure 11-25 (B).

AT.206

Figure 11-25.–Strapped magnetron.
(A) Cutaway view; (B) double strap.

In addition, there are other strapping methods (not shown). All methods are used for the same purpose, but some are more effective than others.

Types of Cavities

The anode of a magnetron is usually a copper block into which resonant cavities have been cut. Several forms of these cavities are shown in figure 11-26.

The capacitance of the cavity is primarily the distributed capacitance between the anode segments forming the resonator; the inductance is distributed around the inner perimeter of the cavity. Each resonator is essentially a parallel resonant circuit, and all are connected effectively in series.

In figure 11-26, the SLOT type anode (A) is effectively a high C/L ratio, the HOLE and SLOT (B) is a medium C/L ratio, and the VANE (C) is a high L/C ratio. The RISING SUN (D) provides excellent separation at high frequencies without strapping.

In the rising sun type anode, the overall resonant frequency lies somewhere between that of the large cavities and that of the small ones. A degree of coupling exists between the cavities of the same size, and the resultant frequency differs from the extremes by an amount depending on the amount of that coupling. Optimum separation between the π mode and the low and high frequencies is obtained through anode block design.

The RF voltage across the large cavities is greater than that across the smaller ones, so the RF field is not uniform. The circulating currents in the large cavities are all in the same direction, and are greater than those in the small cavities; therefore, there is a net circulating current. By applying the proper values of voltage and magnetic field strength, the proper relationship between electron velocity and resonant frequency may be attained.

Output Coupling

In multicavity magnetrons, the output coupling is built into the magnetron, where it is not readily accessible for adjustment. The type and the degree of coupling must be fixed in the design and construction of the magnetron. How-

AT.207

Figure 11-26.—Types of anode blocks.

ever, in order for the technician to properly analyze the operation of radar sets, he must have a basic understanding of the function of the coupling devices, the principles involved in the operation of the devices, and the effects they have on the overall operation of the magnetron and the radar set as a whole.

Because the magnetron is highly evacuated, and the waveguide (when used) is usually pressurized, a pressure seal is required where the power is to be taken out of the magnetron. This seal is probably the weakest point in the entire system for voltage breakdown and power output limitations.

Basically, there are two methods for classifying magnetron coupling systems—by the type transmission line involved (coaxial cable or waveguide), or by the type element used for the coupling (loop or aperture).

LOOP COUPLING.—Loop coupling is normally used for transferring energy into coaxial lines. Figure 11-27 (A) shows one example of the loop method of coupling, where the loop is inserted into one of the cavities of the magnetron. The loop is positioned in an intense magnetic field, so that the plane of the loop is perpendicular to the field; thus maximum energy is transferred to the loop.

The transfer of power is affected by the area of the loop and by the leakage inductance. The loop is usually made of a broad strip of copper, and the wall of the cavity is used as part of the loop.

13484

AT.208

Figure 11-27.–Coupling power out of the magnetron.

Coaxial coupling is limited to relatively low power output circuits, due to the limitations of voltage breakdown and arcing imposed by the coaxial cable.

APERATURE COUPLING.–Transferring power from the magnetron into waveguides normally involves aperture coupling. Such a coupling device consists of two main parts–the TRANSFORMING SECTION of waveguide, and the aperture and WINDOW through which the energy passes from the magnetron to the waveguide. (See fig. 11-27 (B).)

If the guide were connected directly to the magnetron, power transfer efficiency would vary rapidly with any change in frequency or loading conditions. The transforming section of the waveguide functions to provide an impedance match between the magnetron and the waveguide. This matching of impedances permits power to be transferred at a relatively constant level of efficiency throughout the entire range of operation. The matching of impedance is accomplished by making the inside of the first portion of the waveguide section the same shape as the aperture, then gradually changing the section until it has the same shape as the waveguide at the end of the transforming section.

The aperture is normally shaped as an H (fig. 11-27 (B)), with the vertical lines corresponding to broad openings in the ends of one of the cavities. The vertical lines maintain a sufficiently high cutoff wavelength to keep operation of the waveguide in the dominant mode. The horizontal line of the H-shaped aperture is the determining factor in the characteristic impedance of the aperture, and represents a narrow slot through the back of the cavity in the anode block. This aperture effectively functions as a capacity-loaded slot.

The window functions as an air pressure seal and as an RF connection between the inner and outer sections of waveguide. A good window must present practically no loss and no reflections. Reflections at the window are kept to a minimum by selecting the material composition (special glass, mica, or ceramic) and by the diameter and thickness of the window. A non-reflecting window may be considered as a short length of waveguide having the same characteristic impedance as the waveguide into which the window is inserted.

The breakdown strength of the window is greater than that of the coaxial output, but is still not adequate for the higher power magnetrons unless the entire system is built for a very efficient power transfer. Any mismatch caused by improper installation, dirt or grease films, excessive moisture, etc., increases the danger of arcing and the resulting loss of power and possible damage to the components. Mica or a special ceramic material is used for the window to improve the power transfer capability of the system.

Additional Features of Magnetrons

In airborne equipments that use a magnetron, the magnetic field is provided by a per-

13485

manent magnet. Most magnetrons have built-in magnets and are called PACKAGED MAGNETRONS. Thus, whenever a magnetron is replaced, the magnet must also be replaced.

Depending upon the type of magnetron and the type of equipment, it is sometimes necessary to season a new magnetron since it may not withstand the immediate application of full power plate voltage. This is accomplished by subjecting the magnetron for a period of a few hours to filament voltage only. After this warmup period, the plate voltage is applied (at low power settings if possible) and a check is made to determine if the magnetron is arcing. Should arcing be detected, it may be necessary to remove the plate voltage and again subject the magnetron to an additional period of seasoning. The Service Instruction Manual for the specific equipment generally contains information on this phase of maintenance.

Where the magnets are not built in, magnetic polarity should be observed. Theoretically, if the magnetic field of the magnetron is reversed, there should be no change in magnetron operation. This may not always be true since the construction of the magnetron may not be perfectly symmetrical. Thus, if the magnet is removed, it is important that it be reinstalled in its original position. (Generally the polarity of a magnet is indicated, and this may be used as an aid in maintenance.) The magnet should never be removed when the magnetron is operating (nor should the magnetron be operated with the magnet removed) since this would cause electrons to strike the anode at high velocity and result in excessive heating. (With no magnetic field, there is nothing to limit magnetron current.)

The magnetron tube is a delicate unit and must be treated as such. The tube must be handled very carefully. Should it be dropped, or should the tube elements be moved, there is the possibility of a plate to cathode short or a change in spacing of the elements. Either of these will cause the tube to operate improperly or not at all.

Cathodes of magnetrons usually are oxide coated, indirectly heated surfaces. The pulse currents developed are larger than can be produced by thermionic emission alone. The large number of electrons responsible for these currents are developed by secondary emission from the cathode as the cathode is bombarded by high velocity electrons returned by the magnetic field and the RF oscillatory voltage.

Since much of the heating of the cathode is obtained through bombardment of the cathode by the electrons returning to it, the filament voltage is usually reduced after the high voltage is applied. This reduction is accomplished by adding a tapped filament transformer or a series limiting resistor in the circuit. In some equipments the filament voltage is removed completely after anode current reaches a sufficient value.

Metallic cathodes with good secondary emission characteristics have been used satisfactorily. The cathodes are designed with end shields to prevent the escape of electrons from the interaction space between the cathode and the anode block. The magnets, which are made of a special alloy called Alnico, are unusually strong. The field strength required is dependent upon anode potential and operating frequency.

The magnets should not be struck with metallic substances of any hard material because this will cause them to lose some of their magnetism, resulting in a shift in operating frequency, shifting modes of oscillation, and instability of frequency and power output.

Extreme care must be used in handling and even in storing magnetrons. They must not be stored too close together or near other ferrous (magnetic) materials. Carefully observe the instructions in the applicable Service Instruction Manuals and any precautions in or on the shipping container for the magnetrons.

The design of anode blocks determines the frequency and power output. Most anode blocks have cooling fins around the outside for forced air cooling, while other (high power) magnetrons have jackets for liquid cooling.

KLYSTRONS

Klystrons depend upon the formation and control of a high velocity electron beam, and are therefore termed VELOCITY MODULATED TUBES. The tube is usually divided into three functional sections–the electron gun, the cavity/drift space region, and the collector. Klystrons are available in low power models and in high power models. They are also available in basic form and in a modified form called the REFLEX

13486

KLYSTRON. They are used almost exclusively at microwave frequencies as oscillators or as amplifiers.

Basic Klystron

The electron beam is simply a fast-moving stream of electrons expelled from the electron gun into the cavity/drift space regions as shown in (A) of figure 11-28. The electrons forming the beam are emitted from a heated cathode, and flow away from the cathode along converging paths created by the specially shaped electric fields formed by the electrodes. These paths converge to form a beam along an imaginary line extending from the cathode through the drift tubes to the collector. This line is termed the KLYSTRON AXIS.

(A)
THE ELECTRON GUN

(B)
CAVITIES OF CATCHER AND BUNCHER REGIONS

AT.209

Figure 11-28.–Klystron. (A) Electron gun; (B) cavities.

The cathode is a concave section of a sphere located inside one end of a cylindrical metal piece called a FOCUSING ELECTRODE. Just beyond the opposite end of the focusing electrode, the anode cup and first cavity/drift space regions are located. The focusing electrode is maintained at the same potential as the cathode, or at some negative potential determined by the anode potential (which is always positive with respect to the cathode). The positive charge applied to the anode causes the electrons to flow away from the cathode toward the anode, and the negative or zero charge applied to the focusing electrode causes the electrons to move in toward the axis. As a result of the two forces acting on the electrons, they form a converging beam which focuses inside the first cavity/drift space region.

The cavity/drift space region of the klystron is made up of the drift tube and two to four resonant cavities which surround it at intervals along its length. The DRIFT TUBE is an axial-interrupted tube in which the electrons are neither accelerated nor decelerated; its length is about 20 times its diameter. Each interruption along the drift tube, called a GAP, forms the entrance to an associated resonant cavity, and is constructed so that the ends of the drift tube sections protrude into the cavity (refer to (B) of figure 11-28) at opposing high voltage points on the cavity wall. Thus the drift tube tips become the capacitive loading elements in the cavity, and large RF voltages are impressed across them when the cavity is excited at resonance. The cylindrical structure forms the inductive element of the cavity. Such cavities are not necessarily cylindrical; some klystrons use gaps surrounded by cylindrical ceramic envelopes that perform the following three basic functions:

1. Maintain a vacuum with a metal-to-ceramic seal.
2. Maintain the proper spacing of the gap.
3. Facilitate the mounting of a detachable rectangular cavity box.

The electron beam transfers some of its energy to the cavities as it flows along the drift tube section of the klystron, and it carries the balance of its energy out of the cavity/drift space region into an electrode called the

13487

COLLECTOR. The collector gathers the electrons after their function has been accomplished and transfers them out of the klystron into the external circuits leading to the positive terminal of the beam power supply. The large energy content of the partially spent beam must be dissipated by the collector. When the electrons collide with the collector surface, all of their kinetic energy is transformed into thermal energy, which heats the collector. The thermal energy is then transferred to the surrounding environment by cooling the collector with a liquid or by air. (See fig. 11-29.)

Figure 11-29 illustrates the assemblies which comprise a typical high power klystron. Frequent reference should be made to this figure during the following discussion.

This high power klystron requires a strong axial magnetic field to maintain and direct the electron beam throughout the length of the drift tube. This axial field is a result of the prefocus coil, the three body coils, and the collector coil shown in (D). (The field could be produced by permanent magnets, although this feature is seldom used in airborne equipment.)

The electron beam tends to disperse because of mutual repulsion between electrons. The axial magnetic field overcomes the tendency by exerting forces on any electrons that try to move in a direction not parallel to the klystron axis. Thus, electrons attempting to leave the axis are forced to remain within the confines of the beam.

At the beginning of its passage through the drift tube, the electron beam is a continuous stream of electrons moving at a constant velocity. Although it is not confined to a wire, the beam is nevertheless considered to be direct current flowing through the free space enclosed by the drift tube. Ideally, the beam would never touch the drift tube, but in practice there are always some electrons which stray far enough from the center of the beam to be caught by the drift tube walls. Just as a direct current produces no detectable sound as it flows through a headphone, a direct-current electron beam can produce no detectable radiofrequency power as it flows through a klystron. It must be changed in some manner before it can be useful. This is accomplished in the klystron at the cavity/drift tube gaps, which change the relative velocity of the electrons comprising the beam.

It was previously mentioned that a drift tube gap is formed by the ends of drift tube sections which enter the cavity axially from opposite ends. The cavity is designed so that the drift tube tips become its highest voltage points, in order to build up strong RF fields in the gap (fig. 11-28 (B)).

Consider a single electron after it leaves the electron gun region: see axial electron in figure 11-30. As it approaches the first drift tube gap, often called a BUNCHER GRID, the electron absorbs energy from the high voltage power supply, E_{dc}. Notice that instantaneously both buncher grids are at a high d-c potential with respect to the cathode, but there is no RF voltage between the grids at this time. As the axial electron is accelerated toward the first buncher grid, electrons within the first buncher grid structure tend to move away from the axially moving electron and toward the second buncher grid. The movement of electrons within the buncher grid structures constitutes current flow. An RF voltage is created between the buncher grids (labeled $E_{dc} + E_{ac}$ in fig. 11-30) at the point in time when the axial electron is moving in the plane of the first buncher grid. The instantaneous polarities are also shown in figure 11-30.

When the axial electron has passed the first buncher grid and has moved to a point midway between the buncher grids (gap), its field interacts equally on both grids. Electrons in these grid structures are neither repelled nor attracted at this time, and current ceases to flow. The RF potential between the buncher grids (across the gap) reduce to zero volts. E_{dc}, the high d-c voltage applied to the buncher cavity, however, continues to accelerate the electron toward the second buncher grid.

The axial electron then passes the second buncher grid structure; the electrons tend to move away from the axial electron. This constitutes current flow once again, but this time in the opposite direction (shown as $E_{dc} - E_{ac}$ in fig. 11-30). The maximum value of instantaneous voltage occurs when the axial electron is actually passing through the plane of the second buncher grid.

The axial electron now moves beyond the buncher grids into the drift space region. This electron is now moving faster than before it entered the buncher grids, but it has left a positive

13488

UNIT III - DRAWING GEOMETRIC CONSTRUCTIONS

Bisecting an Angle Lesson 2

OBJECTIVE: To learn to bisect an angle, using ruler and compass.

RELATED INFORMATION:

For bisecting the given angle (Fig. 1), strike the arc BC, using A as center and any convenient radius. With a radius approximately equal to AB, and using points B and C as centers, strike arcs intersecting at point D. Draw a straight line from D to A: this will bisect the angle.

FIG. 1

Application:

To locate two end holes in a bracket (Fig. 2), proceed as stated above. Scale the dimensions needed from the drawing shown.

FIG. 2

AT.210

Figure 11-29.—High power klystron, assembly.

13489

AT.211

Figure 11-30.–Buncher grid action.

charge on the second buncher grid, due to E_{ac}, and would be attracted backwards if it were not for the velocity and momentum the electron has acquired.

There are three major points of consideration applicable to buncher grid operation. First, the number of electrons leaving the buncher grids is equal to the number of electrons entering the buncher grids; hence, the electron density remains unchanged. Second, the individual velocities of the electrons leaving the buncher grids are higher because of acceleration by E_{dc}, and their exit velocities are higher or lower than the E_{dc} level (by an amount due to the E_{ac} voltage generated by the axially moving electron itself). Third, E_{ac}, created by the movement of the axial electron, varies in a sinusoidal manner. Hence, the exit electron creates the RF field, E_{ac}, which in turn governs the approach velocity of the entry electron.

Since E_{ac} varies in a sinusoidal manner, the preceding axial electrons approaching the buncher grids will be affected as follows:

1. When the sinusoidal voltage, E_{ac}, is positive, it aids E_{dc} in accelerating the axial electron, so that buncher exit velocity is greater than buncher entry velocity.

2. When the sinusoidal voltage, E_{ac}, is zero, E_{dc} is the only acceleration acting upon the axial electron, so that buncher exit velocity relative to E_{ac} is the same as buncher entry velocity.

3. When the sinusoidal voltage, E_{ac}, is negative, it opposes E_{dc} in accelerating the axial electron, so that buncher exit velocity is lower than buncher entry velocity.

Those electrons in the parts of the beam passing the first gap when it is positively polarized experience an increase of velocity because they flow from a region of negative charge toward a region of positive charge. The negative region repels the electrons and the positive region attracts them, with the result that the velocity and energy content of that part of the beam are increased. The energy gained by the faster parts of the beam is provided by the

13490

driving power furnished to the input (buncher) cavity (fig. 11-29).

Conversely, the electrons in that part of the beam passing through the first drift tube gap during the half cycles when the polarity is negative are forced to travel from a positive to a negative region. As a result, they will be decelerated and surrender some of their energy to the input cavity.

The beam leaving the buncher cavity is continuous and of uniform density, but alternate parts along its length contain electrons having higher or lower velocities than they had before entering the gap. The faster electrons begin to overtake the slower electrons as the beam travels freely down the axis of the drift tube until, at some point a short distance from the gap, the fastest electrons travel in company with the slowest electrons for a brief period of time. During that period of time, optimum "bunching" occurs. The density of the beam now varies periodically at the signal frequency as observed from a fixed point in space and time. In other words, the beam has now become a density-modulated beam. If a gap is located at the point of optimum bunching, the beam can be made to surrender many times as much energy as was originally required to produce velocity modulation; therefore, the klystron acts as an amplifier.

The function of the catcher grid gap (output cavity, fig. 11-30) is to extract energy from the passing beam of electrons. Energy is extracted from the bunched beam by the same method used to velocity modulate it in the first gap. As the beam travels through the catcher gap, the instantaneous gap polarity varies in such a way that the denser portions of the beam are decelerated and the less dense parts of the beam are accelerated. As the different groups of axial electrons were gated through the buncher grids one at a time, some emerged with high velocities and others emerged with low velocities. As they progressed through the drift space, the two groups caught up with each other. At this instant both groups are intercepted by the catcher grids. Although the average power through the klystron has not changed from buncher to catcher cavity gaps, the instantaneous (peak) power is very high when the catcher cavity gaps intercept the combined energy of the merged groups of axial electrons. As a result, there are many more electrons giving up energy to the circuit than there are electrons absorbing energy, and the net effect is to transfer power from the electron beam to external circuits of the klystron.

The preceding paragraphs have described the action of a two-cavity klystron in which the RF power is used to velocity modulate an electron beam so that it can be made to surrender energy to another cavity after traveling a short distance through the drift tube. Experience has shown the klystron having more than two cavities offer advantages in higher gain and higher efficiency.

There is little or no reverse flow of electrons in the drift tube. The fields in the drift tube which are not due to the presence of the beam are so small that, for all practical purposes, there is complete isolation between the output and input cavities. As a result, it is possible to obtain stable operation from four-cavity klystrons with power gains up to one million.

Reflex Klystron

The reflex klystron does not have a buncher and catcher cavity as separate units; a single cavity is employed. The same pair of grids at the entrance to the cavity acts as a buncher grid at one instant and as a catcher grid at the next instant. The control or smoother grid is operated at a positive potential with respect to the cathode. The cavity grids are operated at a still greater positive potential with respect to the cathode. The repeller plate is operated at a large negative potential with respect to the cathode.

Electrons emitted by the cathode are immediately accelerated to high velocities by the positive potential applied to the smoother grid, and a beam is thereby formed. Consider a group of axial electrons, all with approximately the same energy levels, approaching the cavity grids at the same instant. These axial electrons will be highly accelerated by the cavity grids because of E_{dc}. Notice in figure 11-30 that there is no a-c voltage developed between the cavity grids at this point in time; therefore, E_{dc} is the only accelerating voltage acting upon the electrons.

As the accelerating axial electrons approach the first cavity grid, electrons contained within

the metallic cavity-grid structure move toward the second cavity grid because of the mutual repulsion of like charges. The movement of electrons within the grid structures constitutes an electrical current; hence, an instantaneous RF voltage, E_{ac}, is created across the two cavity grids with the polarity shown in figure 11-30. The maximum value of this instantaneous voltage occurs when the axial electrons are actually passing through the plane of the grid structure. The instantaneous polarity of the first cavity grid is now negative, as shown in figure 11-30, and has three effects. First, the effect upon the axial electrons is one of mutual repulsion between like charges. Second, the axial electrons are attracted toward the second cavity grid, which is now positive. Third, any additional electrons approaching the first cavity grid from the smoother grid region will encounter the present negative voltage on the first cavity grid, and their velocity will be reduced because of the repulsion of like charges.

When the axial electrons have moved to a point midway between the two cavity grids, their effect on both grids is equal and the voltage E_{ac} is reduced to zero. These axial electrons, as well as any other electrons approaching the cavity grids from the smoother grid region, are accelerated by a gain-absorbing power from the high voltage power supply.

As the axial electrons approach the second cavity grid, an instantaneous current flow is created once again, but the polarities of the two cavity grids are reversed. The maximum value of E_{ac} occurs when the axial electrons are actually in the plane of the grid structure.

As the axial electrons move away from the second cavity grid, the instantaneous voltage E_{ac} is reduced to zero again. Hence, an alternating voltage is created when the axial electrons move past the cavity grids. This RF voltage causes a change in the velocity of other electrons attempting to pass through the cavity grids.

When the electrons enter the drift space, they come under the influence of the repeller plate. This plate is operated at a highly negative potential with respect to the cathode. Its value is not necessarily fixed, but is so considered during this discussion. Those electrons which were gated through the cavity grid region when E_{ac} was positive possess high velocities and have acquired enough energy to travel far into the drift space, resisting the forces of mutual repulsion centralized at the repeller plate. Eventually, the electron velocity will be reduced to zero, and the electrons will then be attracted back to the cavity grids. (See figs. 11-31 and 11-32.)

Those electrons which were gated through the cavity grid region when E_{ac} was negative not only have low velocity and energy levels, but also passed the grids a half cycle later in time. These low velocity electrons will not travel very far into the drift space region before their velocities are reduced to zero by the forces of mutual repulsion centralized at the repeller plate. (See fig. 11-32.)

Both the fast and the slow axial electrons will be reduced to zero velocity at the same time, but they are widely separated in physical distance. At this point in time consider the forces acting upon the two electrons in the drift space. First, there is the stationary electron located very near the highly negative repeller plate. The forces of attraction centralized at the cavity grids tend to pull this electron back to the grids, but this is very slight compared to the forces of repulsion centralized at the repeller plate. Hence, the electron that originally had a high velocity will be accelerated to high velocity again but toward the cavity grids. Second, there is the stationary electron located very near the highly positive cavity grids. The forces of attraction for this electron are very high, while the forces of repulsion centralized at the repeller plate are comparatively weak. This electron is also attracted back toward the cavity grids, but its velocity is still low. Eventually, the high velocity electron overtakes the low velocity electron, and ideally the cavity grids should be located at the point where this action occurs.

The first and second cavity grids now act as a catcher grid to extract the energy from both electrons as they move past the two grid structures. After the electrons emerge on the other side of the cavity grids, they are once more in the region of the smoother grid. Because of their high velocity and mutual repulsion with respect to the electron beam formed by the smoother grid, these high velocity electrons are deflected toward the shell or body of the klystron (also at a positive potential with respect to the cathode), where they are returned to

18492

AT.212

Figure 11-31.–Reflex klystron, cutaway view.

the plate power supply. The energy extracted by the cavity grids is coupled by the resonant cavity to the output terminals of the klystron.

It was previously stated that the repeller plate voltage was not necessarily fixed. When an alternating voltage such as an audiofrequency is applied directly to the repeller, the rate at which the axial electrons are repelled changes; consequently, the output frequency of the klystron changes or deviates from its average value. This is known as frequency modulation.

In radar equipments using klystrons as the local oscillator, the repeller plate voltage is frequently varied so as to change the frequency of the oscillator. This is the function of the automatic frequency control.

PLUMBING

Many additional microwave components and devices are required to perform specific functions. As a group, these devices are commonly called microwave plumbing devices. Most of these devices make use of sections of waveguide, with internal characteristics and connection methods designed to produce the desired results. This section is devoted to a brief discussion of microwave plumbing devices used for the following purposes:

1. Changing the direction of the signal path (bends, twists, and joints).
2. Connecting signal paths (junctions and couplers).
3. Switching signal paths (duplexer systems).
4. Matching impedances (terminations, reactive devices, and attenuators).
5. Modulation and demodulation of microwave signals (mixers).

Following this section is a brief discussion of the ferrite devices used in microwave systems.

Changes in Signal Path

It is impractical to construct a complete microwave system for an airborne radar set in one straight piece. In an airborne installation,

18493

AT.213

Figure 11-32.–Drift space action in reflex klystron.

each microwave assembly must be mounted in an appropriate location, and the waveguide routed so as to connect them. This requires the use of various bends, twists, and joints in the waveguide structure. (See fig. 11-33.)

In order to transmit energy from one end of a waveguide to the other without reflections or losses, the size, shape, dielectric material, and direction must be constant throughout its entire length. Any abrupt change results in reflections and associated energy losses. By keeping all such changes gradual, the undesirable results can be minimized.

BENDS AND TWISTS.–A gradual bend or twist must have a radius of curvature greater than two full wavelengths in order to minimize reflections. Although the change in direction may be any amount, it is usually made in steps not exceeding 45° each.

A bend is used to change the direction of signal path without changing the orientation of the signal and associated fields and thus the mode of operation. A bend may be made in either the narrow or the wide dimension. When it is desired to rotate the electromagnetic fields, a twist is inserted. Gradual twists are normally used in order to minimize reflections.

When it is necessary that a change be abrupt, special devices must be used. Normally, in a sharp bend, reflections occur and result in considerable power loss. In order to avoid this, the guide is bent twice, at 45° each, a quarter wave apart. The first bend results in a reflection; the second also results in a reflection, but inverted. The combination of the direct reflection and the inverted reflection cancels, leaving the field oriented as though no reflection has occurred.

FLEXIBLE WAVEGUIDE.–To permit use of any special bend or twist required by a specific installation, some sections of waveguide may be made flexible. These sections can be bent or twisted within limits (in most cases the minimum radius of bend or twist is greater than two wavelengths). Because of their flexibility, these sections also help to absorb vibration, permitting shock mounting of units rather than requiring rigid mounting.

Flexible waveguide sections usually consist of a spiral-wound ribbon of brass, the winding having the same cross-section dimensions as the waveguide into which it is inserted. Skin effect keeps current flow at the inner surface; to provide for maximum conductivity, the inside surfaces of the flexible winding are silver plated. To retain flexibility while providing airtight and moistureproof construction, the outside surface is covered with rubber or a flexible insulation material.

Although bends and twists may be incorporated into rigid sections of waveguide, they are often supplied as separate sections, which must then be connected to the main waveguide by joints. Flexible waveguide sections must always be connected to rigid waveguide sections by joints.

JOINTS.–It might seem that joining two sections of waveguide would require only that the sections be the same size and fit tightly at the joint. Irregularities at the joint, however, could set up standing waves and result in energy leakage and dissipation of power.

PERMANENT JOINTS are used only in waveguide sections which do not require disassembly. During the manufacturing process at

the factory, the sections are machined to close tolerances, welded together, and smoothed to a mirror finish on the inside surfaces. This process results in a hermetically sealed joint which has negligible effect on the fields.

If maintenance procedures require that the two sections be disconnected, semipermanent joints are normally used. The most common semipermanent joint is the CHOKE JOINT, illustrated in figure 11-33 (B). The joint consists of two mating flanges, one flat and the other slotted, which connect the waveguide sections at their center. The slot is a quarter wavelength deep at a distance of a quarter wavelength from the point where the walls of the waveguide are joined.

The quarter-wave slot is shorted at the end; the distance down one side and back up the other side is effectively a half wavelength. Thus, the short circuit reflects a short at the point where the walls are joined. Electrically, this creates a short at the junction of the two waveguide sections.

The two sections could actually be separated from each other by as much as one-tenth of a wavelength without creating excessive standing waves or energy loss. Such a separation leaves room to insert a pressurizing seal at the joint. When a seal is to be inserted, the quarter-wavelength distance from the walls to the slot is modified slightly to compensate for the reactances introduced.

In most airborne radar systems, the transmitter is mounted stationary while the antenna must be free to scan or to rotate. This feature requires a ROTATING JOINT, which separates the sections mechanically while efficiently connecting them electrically. (See fig. 11-33 (C).) In a circular waveguide operating in a mode such as $TM_{0,1}$, the fields are symmetrical about the axis. In this system, a simple choke joint may be used; the waveguide rotates, but the field orientation remains fixed. Since the field remains effectively undisturbed, reflections are held at a minimum.

Although this method is satisfactory in theory, most airborne systems use rectangular waveguides, thus requiring a different type of joint. A coaxial cable provides the axial symmetry required for the fields, and also provides the circular cross section required for rotation. In the rotating joint, a probe is the center conductor of the coaxial section. The probe extracts energy from one waveguide section, conducts it through the cable, and injects it into the other waveguide section.

The center conductor is fixed in relation to the stationary section, and the rotating section revolves around it. For electrical connection, the outer conductor can either be fitted with sliding contacts or coupled to the tubing by a half-wave slot. The slot, which is shorted at the end, reflects a short circuit at the junction of the outer conductor sections. With this method, no mechanical connection is required between the outer conductors. The inner conductor of the coaxial section may be supported by insulating washers, if required.

Connecting Signal Paths

Most microwave systems require multiple paths for signal transfer. The connection of signal paths is normally accomplished by the use of junctions and couplers.

JUNCTIONS.–When a section of waveguide is connected into the side of another waveguide, the connection is normally referred to as a T-junction. The junction may be made in either the wide or the narrow side, as indicated in figure 11-34 (A) and (B). When the junction is made in the plane of the H-lines, it is called an H-TYPE junction; when in the plane of the E-lines, it is an E-TYPE junction.

The H-type junction (fig. 11-34 (A)) is effectively a parallel connection with the main line. When the end of the T-section is short circuited at a distance of a half wave from the center of the waveguide, the result is an equivalent parallel circuit. This section will reflect a short circuit at the line and will not allow any energy to pass. Similarly, in the waveguide itself a short circuit is reflected to the center where the E-lines are supposed to be. Since an E-line cannot exist at a short circuit, no energy will pass that point. If the shorted end of the T-section were only a quarter wave from the center of the waveguide, an open section would be reflected there and the passage of energy would be unaffected.

The E-type joint (fig. 11-34 (B)) is effectively a series connection with one side of the main line. In this case, if the section added to the waveguide is a half wave long, it will act as a

113495

AT.214

Figure 11-33.–Waveguide bends, twists, and joints.

A to D via the path B-C. The two paths differ in length by a half wavelength, so that signals arriving by both paths are 180° out of phase and cancel. Any signals traveling to the right in the upper section are in phase, but are lost in the absorbing material.

If the wave in the main guide moves to the left, the two paths by which waves arrive at point D (path BCD and path BAD) are equal in length, and a wave proceeds to the left in the upper guide and is picked up by the test equipment probe. The absorbing material receives little or no energy, since waves to it (paths BADC and BC) cancel. Thus, energy from the transmitter passing to the left in the guide will reach the test equipment connection with a desirable amount of fixed attenuation, but energy picked up by the antenna and passing to the right will not reach the test equipment.

A signal injected at the test equipment probe can travel toward the receiver (which is between the directional coupler and transmitter) but cannot pass to the left toward the antenna.

A one-hole directional coupler is shown in figure 11-34 (D). Coupling from the main guide to the branch is accomplished by the electric and magnetic fields. The phase of the magnetic field is changed by the coupling so that the waves in the branch are canceled in one direction and reinforced in the other. In contrast to the two-hole coupler, the one-hole coupler transmits a wave in a direction opposite to that of the wave in the main line. Proper coupling to obtain the desired directional characteristic depends on the orientation angle between the main guide and the branch guide and the size of the hole between the two guides.

The branch guide is terminated at one end with a resistive material to absorb unwanted power; the other end contains a probe for connection to the test equipment.

Switching Signal Paths

In microwave systems it is sometimes necessary to switch signal paths within a complex system with several modes of operation. One common example of this requirement is found in the waveguide network used with radar antennas. The same antenna is used for transmission and reception, and energy flow in the antenna feed system must be efficient. During transmission, a very high level of energy must flow from the transmitter to the antenna for radiation. During reception, received echoes (which have a very low energy level) must flow from the antenna through the same waveguide to the receiver.

Although the directional couplers previously discussed are capable of switching signal paths, they are not adequate for this task. The power level of the transmitter signal would permit enough leakage through the coupler to damage the sensitive receiver input circuits. The coupler would also permit excessive leakage of the received signal into the transmitter, decreasing the effective overall sensitivity of the system.

In a radar system, the receiver must be disconnected from the signal path during transmission, and the transmitter must be disconnected during reception. Due to the short period of time available for the switching action, the switching device must be automatic and very fast acting. Such a device commonly used in airborne radar systems is the DUPLEXER. A simplified cross sectional view of a waveguide system duplexer is shown in figure 11-35.

The illustrated system consists of a main waveguide section between the transmitter and the antenna, with two branches attached through T-junctions. One branch leads to the receiver, and a TR tube is inserted in this branch. The other branch contains an ATR tube. In most systems the TR and ATR tubes are of the same type; differences in their operation result from differences in installation.

TUBE CHARACTERISTICS.–A TR tube is effectively a gas-filled spark gap tube with three electrodes. Two of the electrodes comprise the main gap (which does the switching); the third electrode is called the keep-alive electrode. The keep-alive electrode is mounted close to one of the main gap electrodes, and is supplied with a relatively high d-c potential.

At sea level pressures of air, approximately 30,000 volts (called the breakdown voltage) are required to break down a spark gap of 1 inch. Once the arc is established, approximately 50 volts (called the running voltage) are required to sustain ionization. Once the running voltage is removed, a period of approximately 10μ sec (called recovery time) is required for deionization. By enclosing the spark gap in a partially evacuated envelope and substituting an appro-

Figure 11-35.–Waveguide system duplexer.

priate gas for the air, the breakdown voltage, running voltage, and recovery time may be reduced. Application of the proper keep-alive voltage keeps the TR tube on the verge of ionization. Thus the magnitude of the ignition spike and the pulse duration may be reduced, while at the same time insuring almost instantaneous firing of the tube for each pulse of the magnetron.

ASSEMBLY OF COMPONENTS.–For optimum overall system efficiency, the power dissipated in the TR and ATR tubes must be minimized. The tubes must maintain a properly matched line while fired; at the same time, they must afford adequate attenuation to prevent excessive leakage into the alternate signal paths. The manner in which these requirements are fulfilled depend on the assembly and tuning of the individual components of the duplexer system (fig. 11-35).

The TR tube is placed an even number of quarter wavelengths from the waveguide. A short circuit existing within the tube reflects an effective short at the entrance of the receiver T-junction. This short prevents the RF pulse from reaching the crystal and receiver circuits, but allows the pulse to proceed unimpeded to the antenna.

The ATR tube is also located an even number of quarter wavelengths from the waveguide. When the transmitter fires, the gap of the ATR tube breaks down and an effective short circuit is reflected across the opening at this T-junction. The wall of the waveguide appears continuous, and the pulse of energy from the transmitter passes unimpeded.

The ATR waveguide section is constructed so that an odd number of wavelengths exists between its shorted end and the opening to the main waveguide. Normally, the tube is deionized, and an effective open circuit appears at the T-junction. A short circuit is thus reflected across the waveguide adjacent to the TR opening (a quarter wavelength away), as shown in figure 11-35 (B). The received signal is thus guided into the TR opening instead of proceeding to the transmitter.

Matching of Impedances

In order to effectively transfer energy throughout an entire waveguide network, it is necessary to maintain a proper impedance match at each transfer point. At every place where waveguides, cavity resonators, or any of the coupling devices are to be joined, the impedances of the input and output devices must be matched for best (but not necessarily maximum) transfer of energy. Improper impedance matching results in undesirable standing waves, loss of power, and decrease of operating efficiency.

The basic principles of impedance matching are discussed in chapters 4 and 12 of Basic

13499

Electronics. A thorough review of these principles may prove helpful before proceeding with this discussion.

The characteristic impedance (Z_0) of a waveguide is not as easy to define as that of a coaxial line. The characteristic impedance of a waveguide is approximately equal to the ratio of the strength of the electric field to the strength of the magnetic field. This ratio is equivalent to the voltage to current ratio in coaxial lines on which there are no standing waves.

The lowest characteristic impedance of a circular waveguide is about 350 ohms. In a rectangular waveguide, it may be any value, depending on the dimensions of the waveguide and the frequency of the electrical energy. In this guide, it is directly proportional to the narrow (b) dimension when the wide (a) dimension and the frequency are fixed, and may vary from approximately 0 to 465 ohms.

On a waveguide there is no practical place to connect a fixed resistor to terminate it in its characteristic impedance as there is on a coaxial cable. However, there are a number of special arrangements which accomplish the same purpose.

In many cases it is desirable to match the impedance of the guide in order to insure a minimum of reflection. On the other hand, there are many instances where it is desirable for all the energy to be reflected from the end of the waveguide. Both of these, and some other methods of matching or modifying impedances of the guides, are discussed below.

MINIMUM REFLECTIONS.–One method of terminating a waveguide for minimum reflections consists of filling the end of the guide with a graphite-sand mixture, as shown in (A) of figure 11-36.

As the fields enter the mixture, currents flow in it and create heat, which is instrumental in dissipating energy. None of the energy thus dissipated as heat is reflected back into the guide.

Another method for terminating a waveguide is to use a wedge of high resistance as shown in (B). The plane of the wedge is placed perpendicular to the H-lines. When the H-lines cut the wedge, a voltage is induced; the current produced by the induced voltage produces an I^2R loss. Similarly, E-lines produce current flow and an I^2R loss. These losses are dissipated in

AT.217

Figure 11-36.–Termination for minimum reflections.

the form of heat, and very little energy is permitted to reach the closed end to be reflected.

These terminations are used as transmitter dummy loads for testing and shop operation. They are generally constructed with external cooling fins for better heat dissipation.

MAXIMUM REFLECTIONS.–When it is desirable to terminate the waveguide in such a manner as to obtain maximum reflection of energy from the end of the waveguide, there are several methods that may be used. Some of these are shown in figure 11-37.

One method is to weld a permanent metal shield (plate) at the end of the waveguide, as shown in (A). When it is necessary that the end be removable, a removable end plate is attached to the end of the guide. For this method to be satisfactory, the contact between the guide and the end plate must be exceptionally good in order that the H-field will not be attenuated when current flows.

Perfect contact is not required when the connection is made at a point of minimum current. (This point is located a quarter wave from the end.) When connection is made at this point, a cup is used (as in (B)) instead of the end plate. This cup is a quarter wave long and large enough to fit over the end of the guide. The voltage between opposite sides of the cup opening is high; but as the reflected H-field cancels the incident H-field, the resulting current is very small and power loss is at a minimum.

13500

AT.218

Figure 11-37.–Termination for maximum reflections.

When the end must be adjustable, the contact must be nearly perfect. However, it is impossible to get a perfect contact. The best arrangement, one which is similar to the choke joint previously explained, consists principally of an adjustable plunger which fits into the guide as shown in (C). The walls of the waveguide and the plunger form a half-wave channel. The half-wave channel is closed at one end and reflects a short circuit across the other end, where a perfect connection is supposed to exist between the wall and the plunger. The actual physical contact is made at a quarter-wave distance from the short circuit, where the current is minimum due to the standing waves. This makes it possible for the plunger to slide loosely in the guide at a point where the contact resistance to current flow is very low.

REACTIVE DEVICES.–Some devices which are used in radar introduce inductance or capacitance into the circuit. Sometimes these reactances are deliberately introduced. Other times when they are present and not desired, they can be tuned out with small fins or plates in a waveguide.

Figure 11-38 shows a number of reactive plates which are deliberately used to introduce capacitance or inductance into a waveguide. In (A) the edges of the plates are parallel to the E-lines. The electric field causes current to flow along the edges. The current flow causes a magnetic field to be generated, and thus the partition acts as an inductance. The partition also causes higher order modes; but since the waveguide is too small for these modes, they are rapidly attenuated and are not propagated. This causes a small loss of power. The amount of inductive reactance produced by these plates depends on the spacing between them. The wider the spacing, the greater the inductive reactance, and the smaller the effect on the fields.

In (B) the edges of the plates are at right angles to the E-field. Electrons accumulate first on one edge and then on the other, and the plates act as a capacitor. Higher modes are produced (as with the inductive plates); and the wider the spacing between the plates, the greater the capacitive reactance.

From these facts it would seem that a resonant circuit might be produced by combining both types of plates and leaving a small opening in a large guide, as shown in (C). This is approximately true, provided that the dimensions are correct. Such a waveguide would, in effect, have a parallel resonant circuit connected across it.

Mixing Microwave Signals

The usual function of the mixer in a superheterodyne receiver is to combine the frequency of the incoming signal with that of the local oscillator, and to produce from this combination a third (IF) frequency. The IF is usually much lower than either of the two input frequencies. The IF is then amplified and used to carry the impressed intelligence through the rest of the RF circuits. (The basic principles of superheterodyne receivers are discussed in Basic

AT.219

Figure 11-38.–Reactive plates in waveguide, $TE_{1,0}$ mode.

Electronics.) Use of vacuum tube mixers is usually restricted to receivers in and below the UHF range. At microwave frequencies, the mixer is almost always of the crystal type.

Crystals are extremely delicate, and must be well protected by the TR device as discussed previously. Echo signals of a microwave radar system, after passing through the TR device, are applied to the crystal mixer. Local oscillator voltage is also applied to the mixer. Signals at the intermediate frequency are derived at the mixer output during the time of each return echo.

SINGLE-ENDED MIXERS.–Figure 11-39 illustrates the important features of a single-ended mixer used in the 10-cm frequency range with coaxial line inputs. Part (A) is a cutaway pictorial representation; part (B) illustrates the equivalent circuit.

Echo signals are coupled into the transmission line section between the TR cavity and the crystal by means of a coupling loop which penetrates a short distance into the cavity. The crystal fits snugly into the inner conductor of the line and is held concentric with the outer conductor by means of a dielectric bead. The local oscillator signal is introduced into the mixer assembly by means of a coupling probe located approximately a quarter wave (at the local oscillator frequency) from the coupling loop in the TR cavity. A high impedance in the direction of the cavity is thus presented to the local oscillator signal at the probe. The strength of the local oscillator signal at the crystal may be changed by varying the distance the probe extends into the main line. Power from the local oscillator is conducted to the probe via a section of transmission line.

Connection between the crystal and the inner conductor of the line section carrying IF signals is provided by a spring contact. The half-wave RF choke appearing on the IF side of the crystal provides an electrical short circuit for radio-frequency signals at point B. The d-c return path for crystal current is provided at the RF end of the mixer assembly by the TR coupling loop and at the IF end by a shunt inductance element located in the grid circuit of the input IF amplifier stage (not shown).

A two-wire equivalent circuit of the mixer is given in figure 11-39 (B). If small losses in the RF line and TR cavity are ignored, the portion of the RF transmission system between antenna and output terminals of the TR cavity may be represented by a signal current source I_s in shunt with the characteristic resistance R_c of the transmission line. Because the local oscillator is loosely coupled to the main line, negligible admittance appears in shunt with the lines A and B in the figure. Elements L1 and C1 represent the RF choke at the IF end of the crystal and are series resonant at the echo signal frequency. Hence, line B is terminated by the crystal at the echo signal frequency. For maximum receiver sensitivity it is important that essentially all the echo power available at the TR device be transferred to the crystal. The

68502

AT.220

Figure 11-39.–Single-ended 10-cm coaxial-fed mixer.

crystal should therefore present a matched load termination to the main line section. Fortunately 10-cm crystal units, when operated with 5/16-inch 50-ohm coaxial lines, provide essentially a matched RF load for the line. An impedance changing device between the crystal and the TR cavity is therefore usually unnecessary.

Because the local oscillator is loosely coupled to the main line containing the crystal, an appreciable mismatch of impedance exists on the local oscillator line at the coupling probe. A large impedance mismatch is, in general, undesirable because of the wide variations in the local oscillator load impedance (and hence power output) that result when the oscillator frequency is varied. A good impedance match is particularly important if the line between the local oscillator and the probe is long. To insure a rela-

tively constant load impedance for the oscillator, a resistance disk type of attenuator is often inserted in the local oscillator line, as shown in (A), in order to terminate the line section between the oscillator and the disk in its characteristic resistance. An alternative to the resistance disk is a length of "lossy" cable, which may be inserted between the local oscillator and the mixer assembly. (NOTE: Lossy cable uses resistance wire for the center conductor. An example of lossy cable is RG-21/U.)

Mixer assemblies often include, in addition to the circuit that supplies IF echo signals, a separate mixer for generating IF signals for the automatic frequency control circuit. An example of a 3-cm mixer assembly of this type is shown in figure 11-40. Part (A) is a cutaway pictorial representation; part (B) is an equivalent schematic.

Although this mixer uses two mixing crystals and separate waveguide channels, it is classed as a single-ended mixer because the output signals are independent of each other (due to the use of different signal inputs). Actually, this circuit could be appropriately described as two single-ended mixers.

Local oscillator power and RF echo signals from the TR cavity are coupled into waveguide 1, which serves as the echo signal channel. A crystal extends between the top and bottom walls of the guide, the lower end of the crystal being isolated from the guide by means of a dielectric washer. Echo signal voltages in the IF band appear between the lower end of the crystal and the waveguide, and are conducted to the input circuit of the IF amplifier, usually by coaxial cable.

Waveguide 3 is similar in construction to waveguide 1 and serves as the AFC channel. Power from the local oscillator and a small amount of the transmitter power are applied to the AFC crystal. IF signals for the AFC circuit are derived at the lower end of the crystal mount, as before. Attenuation between the main guide and guide 3 is provided by means of a circular waveguide section operating below cutoff. A disk type attenuator is sometimes included in the circular section to further reduce the amount of transmitter power reaching the mixer assembly.

The local oscillator tube is mounted above waveguide 2 in a manner that permits the local oscillator output probe to extend a short distance into guide 2. The coupling probe may be displaced slightly from the center of the transverse axis of the guide. This method is used to obtain a load impedance for the oscillator which provides a reasonably uniform power output over the tuning range.

Local oscillator power is coupled from guide 2 into guides 1 and 3 through coupling apertures located in the side walls of the guides. A matching post and tuning screw extending from the top and bottom walls of the guides at the aperture locations serve to regulate the amount of local oscillator power coupled to the mixer circuits.

For optimum performance of the radar system, the echo signal channel of the mixer should provide a matched load impedance to the waveguide transmission system. The elements that determine the mixer input impedance are shown in the equivalent circuit (B). The equivalent circuit is derived by dividing waveguide 1 into three sections of lengths (Bd_1, Bd_2, and Bd_3), and representing the sections by equivalent lengths of transmission lines (lines A, B, and C). The signal current generator I_s in shunt with R_c in the equivalent circuit accounts for the portion of the RF system between antenna and mixer. The coupling aperture between the local oscillator and mixer guides (guides 1 and 2) is represented by a variable inductance L, and in shunt with L is an impedance Z which accounts for the impedance seen in the direction of the local oscillator guide. The parallel combination of L and Z terminates a quarter-wave section of line which is in shunt with lines A and B. At the echo signal frequency, the impedance of L and Z in parallel is maintained small enough (in comparison with the characteristic resistance of the quarter-wave line) to make the input impedance of the quarter-wave section extremely high; hence, the amount of echo signal power entering the local oscillator guide is extremely small.

The crystal is located at the junction of lines B and C; across the crystal output terminals is a series RLC circuit. (The counterpart of the RLC combination is an RF choke in the IF output lead of the mixer. The choke prevents RF signals from entering the input circuit of the IF amplifier.)

The length of the shorted-end line C must be such that the input admittance of line C, in shunt with the RF admittance of the crystal, provides essentially a matched load for line B.

13504

AT.221

Figure 11-40.—Single-ended 3-cm waveguide-fed mixer.

Varying the length of line C changes the susceptance component of the total admittance at the crystal location. A length of approximately $\lambda/4$ is usually preferable in order to minimize changes in admittance with frequency variations.

BALANCED MIXERS.–The noise introduced into the input circuit of a microwave receiver by the local oscillator may be reduced appreciably through use of a balanced mixer. An input circuit of this type employs two crystal mixers connected so that the local oscillator voltages applied to each crystal are in phase and the echo signal voltages at each crystal are phased 180°. This method of circuit connection causes the IF components of local oscillator noise to cancel in the IF amplifier input circuit, and the IF components of the signal to add. Because of their ability to suppress local oscillator noise and because of certain additional advantages to be discussed later, balanced mixers are often preferable to single-ended mixers. They are presently finding wide use in microwave radar systems.

The basic principles of a balanced mixer may be explained from the diagram of figure 11-41, which shows two crystals mounted a half wavelength apart (at the signal frequency) between conductors of a coaxial line section. Each crystal is located a quarter wave from the nearer end of the line, and the local oscillator signal is probe coupled to the line at a point midway between the crystals. The output terminals of the crystals are connected to an IF transformer, the primary winding of which is balanced to ground. The signal current generator I_S in shunt with resistance R_C accounts for signals entering the mixer from the TR device.

AT.222

Figure 11-41.–Coaxial line balanced mixer circuit.

The local oscillator coupling probe gives rise to two waves traveling in opposite directions in the coaxial line. Assume that the local oscillator frequency at the TR device presents a short circuit to the local oscillator wave traveling to the left, and that the crystals have identical RF impedances equal to twice the characteristic resistance of the line. Then equal-amplitude, in-phase, local oscillator voltages appear at the crystals. Because of the half-wave spacing between crystals, the RF echo signal voltages at the crystals are also of equal amplitude but are 180° apart in phase. An in-phase relation between the local oscillator and echo signal voltages produces an IF signal voltage of one phase, and a 180° phase relation between the local oscillator and echo signal produces an IF signal voltage of opposite phase. Thus the two IF echo signal voltages add in the balanced input circuit of the IF amplifier. Because the noise that accompanies the local oscillator signal produces voltage components that bear the same phase relation to the local oscillator voltage at each crystal, the corresponding IF components of noise at the output of each crystal are in phase, cancel, and hence produce no resultant noise voltage across the IF transformer.

In order to realize full benefit from use of a balanced mixer circuit, the crystal should have similar RF impedance as assumed above, and in addition they should have similar conversion gains. Under these conditions of operation, only one-half the available RF power is applied to each crystal; but since the power in the IF signals from the two crystals add together, the total IF power is the same as that obtained from a single-ended mixer. Since IF components of the local oscillator noise are completely eliminated, maximum reduction in overall noise figure is obtained.

An imbalance in conversion gain yields an imbalance in the IF signal voltages obtained from the crystals, and also an imbalance in the IF components of local oscillator noise voltages at the crystal output terminals. However, since the IF signal voltages are additive and the local oscillator noise components are subtractive,

small imbalances in conversion gain do not seriously affect the overall receiver noise figure.

More important are the effects of a difference in the RF admittances of the crystals. An imbalance of this type causes both the echo signal power and the local oscillator power to divide unequally between the two crystals. As a result, the IF signal power obtained from the mixer is appreciably reduced, and the IF components of local oscillator noise are prevented from canceling completely. Crystals intended for use in this type of mixer must be carefully selected on the basis of equal RF admittance in order to insure most satisfactory operation.

MICROWAVE FERRITES

The most common ferromagnetic substances (iron, nickel, cobalt, and their alloys) are good electrical conductors. They cannot, therefore, be used as magnetic materials at the higher frequencies because of eddy current losses. Ferrites, however, are not subject to eddy currents. Even though their magnetic susceptibility is much lower than that of the ordinary ferromagnetic substances, they can be used at the higher frequencies. Ferrites are unique because they have useful magnetic properties and are also insulators. RF fields can penetrate a ferrite; this is not possible in a conducting magnetic substance.

At microwave frequencies, the greatest use of ferrites is in nonreciprocal propagation devices. Nonreciprocal devices can be used to isolate a signal source from its load. A magnetron or other microwave signal source operating into a varying mismatched load (as in the case of a scanning antenna which is fed by a line with rotating joints;) tends to "pull" in frequency. If the reflected energy caused by mismatch is absorbed or diverted before it reaches the source, the source will "see" a constant load.

Nonreciprocal ferrite devices make use of the interaction of the electron's spin with an external magnetic field.

Ferromagnetic Resonance

When a ferrite is placed in an external magnetic field, the "atomic" magnets within the ferrite tend to line up with the external field. A spinning electron has gyroscopic properties. When an external force attempts to change the spin axis, the electron precesses. Any gyro has a preferred or natural precession frequency which is proportional to the strength of the external field. By proper choice of ferrite material and external field strength, the natural precession frequency can be made to coincide with any selected microwave frequency.

An electromagnetic wave traveling down a waveguide will produce, at a point off the centerline of the guide, a rotating magnetic field. This is illustrated in figure 11-42(A). As the wave advances from right to left, the stationary point A sees a clockwise rotating magnetic field. A wave traveling from left to right will produce, at point A, a magnetic field with counterclockwise rotation.

A slab of ferrite placed off center in a waveguide, as shown in (B), will act as a one-way device at a frequency which depends on the external magnetic field strength. If the ferrite's preferred electron precession frequency matches the frequency of an RF wave traveling from left to right in the guide, the ferrite will absorb most of the energy in the wave; the rotating magnetic field as seen at point A will aid electron precession. The electrons will

AT.223

Figure 11-42.–Ferromagnetic resonance.

13507

precess vigorously and convert the RF energy to heat. This phenomenon is known as ferromagnetic resonance. A wave traveling from right to left will be attenuated very little because its rotating magnetic field will oppose electron precession. The one-way device shown is a RESONANCE ISOLATOR.

Faraday Rotation

If a plane-polarized wave is propagated through a circular (or square) waveguide containing an axially mounted ferrite rod, the plane of polarization will be rotated when a magnetic field is applied parallel to the direction of propagation. The amount of rotation will depend on the strength of the applied field and the dimensions of the ferrite rod. The sense or direction of rotation will depend only on the polarity of the magnetic field. Figure 11-43 illustrates Faraday rotation.

Faraday rotation occurs as the wave travels past the ferrite rod. The plane of rotation is shifted in the same direction, regardless of the direction of wave propagation, as can be seen by comparing (A) and (B) of the figure.

An isolator which uses the Faraday effect is shown in figure 11-44 (A) and (B). A plane-polarized wave comes down the guide and goes through a rectangular-to-round waveguide transition. As the wave passes the ferrite in (A), its plane of polarization is rotated 45° clockwise, and it leaves through the rectangular guide. If a wave comes down the guide in the reverse direction, it will also be rotated 45° clockwise (as viewed from the left) as shown in (B). The wave will be 90° from the transmission plane of the rectangular guide (the guide will be cut off for this polarization), and the wave will be reflected. Properly oriented vane type absorbers will absorb this energy without affecting waves traveling in the other direction.

In isolators designed to handle high power, the reflected wave can be coupled out to a separate power-absorbing load. An isolator of this type is shown in figure 11-44 (C).

Switches

A Faraday isolator can be modified to act as a single pole, double throw, WAVEGUIDE SWITCH. In the waveguide switch, the output end of the device has two rectangular output

AT.224

Figure 11-43.–Faraday rotation.

guides 90° apart. Each output guide is 45° from the input guide at the other end of the device. An electromagnet supplies the external field. Switching is accomplished by reversing the direction of current flow in the electromagnet. Current in one direction causes the RF wave polarization to be rotated clockwise 45°. Electromagnetic current in the opposite direction causes the wave polarization to rotate 45° counterclockwise. In each case, only one of the output guides will accept the RF wave. Switching times of less than 1μsec are possible. Isolation between the output guides (if they are properly terminated) is on the order of 40 db. This type of switch can be used to switch a transmitter between two antennas.

Circulators

A CIRCULATOR is a device which allows one-way propagation of signals through it. It

UNIT III - DRAWING GEOMETRIC CONSTRUCTIONS

Dividing a Line Into a Number of Equal Parts Lesson 4

OBJECTIVE: To learn to divide a line into any number of equal parts.

RELATED INFORMATION:

TO DIVIDE A LINE INTO SEVEN EQUAL SPACES

FIG. 1

The illustration given here will show how to divide a line into seven equal parts: The same method can be used for any number of equal parts. In Fig. 1, the given line is AB. Draw the light line AC at an angle approximately equal to 30°. On line AC, step off with your compass seven equal spaces, of any convenient length. (All seven parts on line AC must then be equal to that length.) Connect the last, or seventh, part with B. Through the other points on line AC, draw lines parallel to BC. The points thus found on line AB will divide AB into seven equal parts.

Application:

To drill six holes, equally spaced, on a piece of sheet steel (Fig. 2), proceed as stated above. Scale any dimensions needed from the drawing shown.

APPLICATION- SIX HOLES EQUALY SPACED

may have several input-output ports. Figure 11-45 is a schematic of a four-port circulator. The arrow shows direction of power flow within the circulator. Power entering port 1 leaves by port 2 only; power entering port 2 leaves by port 3 only, etc. This one-way power flow between ports results from rotation of the signal polarization between ports. Each port is so oriented that it will be cut off for all signals except those which entered the port just before it. Each port, if it is properly terminated, will accept all of the power from the preceding port. A four-port circulator may be used as a radar duplexer. The load at port four absorbs any local oscillator signal from the receiver and prevents it from being radiated.

ANTENNAS

An antenna is a special type of electrical circuit intentionally designed to radiate and/or receive electromagnetic energy. In an ordinary circuit, the inductance, capacitance, and resistance are lumped constants and therefore the electromagnetic field is confined to the circuit where it performs useful work. In an antenna, the L, C, and R properties are distributed and the electromagnetic field is not confined–it is spread

13509

AT.226

Figure 11-45.–Circulator.

out and tends to escape or radiate. It is this radiated field which provides the link between a transmitter and receiver.

The method of propagation is of interest, but of more concern to the technician is how the energy can be directed (the radiation pattern) and concentrated (the beamwidth), and how the efficiency (gain) can be enhanced. A familiarity with the basic types of antenna systems and the polarization of the transmitted wave provides a background of information and an appreciation of the problems involved in the selection of a suitable antenna type for a specific application.

Several of the more common antenna configurations with typical operating frequency ranges and radiation patterns are shown in figures 11-46 and 11-47. These figures should be consulted throughout the discussions which follow. Table 11-2 lists the normal polarization and directional characteristics of certain antenna types.

While the simplest type of antenna is the bidirectional dipole, limitations in directivity, frequency passband, and gain somewhat restrict its use. Other dipole configurations such as the ram's horn and the corner reflector are used for special applications.

Although the crossed dipole, the whip, the top-loaded vertical, or the "J" is sometimes used, the ground plane antenna is probably the most popular when reception or transmission

AT.227

Figure 11-46.–Antenna selection based on typical operating frequencies in megahertz.

13510

AT.228

Figure 11-47.–Typical radiation patterns for selected types of antennas.

must be equally effective in all directions (omnidirectional). For much higher frequencies, the biconical or the disk horn is recommended.

The log periodic, helical, and flat-spiral antennas are noted for their extremely wide (as high as 20:1) operating frequency range.

When space is not a controlling factor, the rhombic and the "V" type are often used to provide high gain and directivity. Both types normally are bidirectional. The rhombic can be made unidirectional by terminating the ends of the legs with a noninductive resistor. The "V" is made unidirectional by the use of another "V" spaced an odd number of quarter wavelengths behind the original. Typical legs for the rhombic are three to four wavelengths; for the "V" type, legs of eight wavelengths are not uncommon.

The parabolic antenna is capable of producing high gain and excellent directivity. Although screen mesh or even a grid or rods may be used where wind resistance is a design factor, the reflector element generally consists of a solid surface. Physically the reflector should be several wavelengths in diameter. Additional gain also can be obtained by mounting a hemispherical reflector in front of the dipole, provided its surface area does not appreciably shadow the rear parabolic reflector. The radiating element may be a dipole, a horn, or other suitable radiator.

13511

Table 11-2.—Antenna characteristics.

Type	Usual polarization	Directivity
Dipole	Horizontal	Bidirectional
Dipole array	Horizontal	Unidirectional

CHAPTER 12

SERVOSYSTEMS

There are many types of servosystems in use, such as electronic, hydraulic, and amplidyne. There are also many different variations and combinations of these basic types. It is beyond the scope of this training manual to describe all systems in detail, since each servosystem is designed for a specific task. Therefore for each specific system the applicable manual should be referenced.

It is recommended that the basic theory of synchros and servomechanisms as discussed in Basic Electricity, NavPers 10086-B be reviewed before proceeding in this manual.

BASIC TYPES OF CONTROL

A servomechanism, in carrying out its orders, accomplishes its task by exercising control over a source of power. Control implies the conditional use of an external source of power, which in most cases is substantially greater than the controlling power. Almost unlimited quantities of mechanical or electrical power can be controlled by opening or closing a simple valve or switch.

Since a servomechanism is a device for exercising control of some external source of power, it is well to consider the various basic types of controls and their characteristics. A control system may encompass the control of electrical, mechanical, hydraulic, pneumatic, or thermal units, or of various combinations of different units.

The simplest form of control can be illustrated by the elementary electric circuit shown in (A) of figure 12-1. The circuit contains a source of power; a switch, or controlling device; and a load consisting of a heater element. The components are connected in series; and when the switch is closed, energy flows to the load and performs useful work; when the switch is opened, the energy source is disconnected from the load. Thus, the flow of energy is either zero or a finite value determined by the resistance of the circuit. Operation of this general type is called discontinuous control.

In (B) of figure 12-1 the circuit shown is modified by substitution of a rheostat for the switch; and the circuit now provides continuous control. By displacing the rheostat contact, the circuit resistance is varied continuously over a limited range of values. The energy expended in the load is then varied or regulated over a corresponding range rather than by intermittent, or on-off, action as in discontinuous control. These examples represent a fundamental property of control systems in general; the energy required to control the system is small compared with the quantity delivered to the load.

As discussed above, the power source is controlled directly by the manual adjustment of a switch or of a rheostat. In more complicated systems, control signals are applied to the power device by the action of an automatic electrical or mechanical device rather than by manual means. The device which develops the control signals is called an automatic controller, and the entire system is known as an automatic control system.

Automatic control systems can be divided into two basic types: open-loop and closed-loop systems. An example of an automatic open-loop control system is an electric timer used to control the action of the heating element. (See fig. 12-1 (C).) Although the heater is switched on and off automatically, the temperature of the oven in no way affects the switching action of the timer. The initiating action (timer) is independent of the results obtained.

13513

If a bimetallic spring type thermostat is substituted for the switch as shown in figure 12-2, the temperature of the oven will control the power applied to the heater. When the temperature rises to a predetermined level, the thermostat will open the circuit. When the temperature falls slightly below this point, the spring cools, closing the contacts, and the heater again begins operation. The controlling device is affected by the results of the load and is known as a closed-loop system.

All controls described are used to regulate the power to the heater. Thus, they may be classified as regulating controls. An example of their application in electronic equipment may be found in the regulation of pressure, temperature, and speed.

Another type of control is the positioning control. As the name implies, the positioning control is used to position a shaft or some other form of load. The basic fundamentals applicable to regulating controls also apply to positioning controls. Thus, positioning controls may be continuous or discontinuous, open-loop or closed-loop, and manual or automatic. However, most controls with which the technician is concerned are of the continuous, automatic, closed-loop type.

To insure a thorough understanding of this type of control, briefly review what it encompasses. A block diagram of such a system is shown in figure 12-3. An order is issued by the

AT.229

Figure 12-3.–Block diagram showing continuous, automatic, closed-loop type of control system.

command order device to change the position of the load to a certain location. The error or difference measuring device receives the order, compares it with the present position of the load, and issues an order to the controlling device based on the difference between the ordered location and present location. This is a continuous process until the load reaches the ordered position.

A type of automatic closed-loop positioning control system frequently used in aviation electronic equipment is the servomechanism. A servomechanism may be defined as a feedback automatic control system that measures the output, compares it with the input, and uses the resulting error signal to control comparatively large amounts of load power.

BASIC SERVOMECHANISMS

The essential components of a servomechanism are the data transmission system, the servocontrol amplifier, and the servomotor. These components are shown in the block diagram of figure 12-4 and are discussed in the following paragraphs.

The functions of the data transmission system are as follows:

1. To measure the servo output.
2. To transmit or feed back the signal, which is proportional to the output, to the error detector (a differential device for comparing two signals).
3. To compare the input signal with the feedback signal to the servo.
4. To transmit to the servoamplifier a signal which is proportional to the difference between the input and output signals.

The signal obtained by comparing the servo input and output is called the servo error, and is represe. y the sumbol E. Figure 12-4 shows that the servo error (E) is the difference between the input (θ_i) and the output (θ_o). This is stated mathematically as $E = \theta_i - \theta_o$.

In many servosystems the physical location of the servo input device and output device are remotely located from each other and may also be remotely located from the servoamplifier. This requires some means of transmitting the output information back to the device receiving the input command. This transmission system as well as the comparing device (called an error detector) is part of the data transmission system.

The function of the servoamplifier is to receive the error signal from the error detector, amplify it sufficiently to cause the output device to position the servo load to the commanded position, and to transmit the amplified signal to the servomotor.

The servomotor functions to position the servo load. The motor must be capable of positioning the load so as to require a minimum response time based on the requirements of the system.

ERROR DETECTORS

The component of the data transmission system that compares the input with the servomechanism output is the error detector. An error detector can be either a mechanical or an electrical device. A simple form of a mechanical error detector is the differential. However, most error detectors are electrical devices because of their adaptability to widely separated or remotely installed components. Most of the electrical devices used are of either the potentiometer (resistive) or one of several magnetic devices.

Electrical error detectors may be either a-c or d-c devices depending upon the requirements of the servosystem. An a-c device used as an error detector must compare the two input signals and produce an error signal of which the phase and amplitude will indicate both direction and amount of control necessary for correspondence. A d-c device differs in that the polarity of output error signal determines direction of the correction necessary.

Error detectors are also used extensively in gyro stabilized platforms and rate gyros. In

13145C1

AT.232

Figure 12-4.–Simplified block diagram of a servomechanism.

the stabilized platform, synchros are attached to the gimbals. Thus, any movement of the platform around the gyro axes is detected by the synchro and the error voltage is sent to the appropriate servosystem.

In rate gyros, the E-transformer (discussed later) is commonly used to detect gyro precession. It is extremely sensitive to very slight changes, but its movement is limited to a very small amount. Thus, it is extensively used with constrained gyros.

POTENTIOMETER

Potentiometer error detector systems are generally used only where the input and output of the servomechanism has limited motion. They are characterized by high accuracy, small size, and the fact that a d-c or an a-c voltage may be obtained as the output. Their disadvantages include limited motion, a life problem resulting from the wear of the brush on the potentiometer wire, and the fact that the voltage output of the potentiometer changes in discrete steps as the brush moves from wire to wire. A further disadvantage of some potentiometers is the high drive torque required to rotate the wiper contact.

An example of a balanced potentiometer error detector is shown in figure 12-5. As stated above, the purpose of the circuit is to give an output error voltage which is proportional to the difference between the input and output signals.

The command input shaft is mechanically linked to R1 and the load is mechanically linked to R2. An electrical source of 115 volts a.c. is applied across both potentiometers.

When the input and output shafts are in the same angular position, they are in correspondence and there is no output error voltage. If the input shaft is rotated, moving the wiper contact of R1, an error voltage is applied to the control amplifier. This error voltage is the difference of the voltages at the wiper contacts of R1 and R2. The output of the amplifier causes the motor to rotate the load and the wiper contact of R2 until both voltages are equal; thus, there is no output error voltage.

Figure 12-5 illustrates R1 and R2 grouped together. In actual practice the potentiometers may be positioned remotely from each other, with R2, the output potentiometer, being located at the output shaft of the load. This remote location of one of the components does not remove it from being a part of the error detector.

E-TRANSFORMER

A type of magnetic device which is used as an error detector is the E-transformer. Its application is useful in systems that do not require the error detector to move through large angles. A simplified drawing, which is one of several possible devices in this category, is shown in figure 12-6.

13516

AT.233

Figure 12-5.–Balanced potentiometer error detector system.

The primary excitation voltage is applied to coil A on the center leg of the laminated core. The coupling between coil A and the secondary windings, coils B and C, is controlled by the armature which is displaced linearly by the input signal. At the position of the armature where the coupling between the windings is balanced, the output voltage is minimum because of the series-opposing connections of the secondary windings. The phase of the output voltage on either side of the voltage null differs by 180°, and by proper design of the transformer the amplitude can be made proportional to the displacement of the armature from its null voltage position. This type of error detector possesses the advantages of small size and high accuracy, but has the disadvantage of permitting only limited input motion.

AT.234

Figure 12-6.–E-transformer error detector.

CONTROL TRANSFORMER

Synchros have been developed to a point of relatively high accuracy, low noise level, reasonably small driving torques, and excellent life. These qualities are also applicable to the synchro control transformer. A primary advantage over other types of error detectors is its unlimited rotation angle; that is, both the input and the output to the synchro control transformer may rotate through unlimited angles. Among the disadvantages of synchros (including the synchro control transformer) are the large size necessary to maintain high accuracy, the power consumed, and the fact that the output supplied to the servocontrol amplifier is always a-c modulated with the servo error and must be demodulated in the servocontrol amplifier if it is to be applied to a d-c servomotor.

The synchro data transmission system is comprised of a synchro transmitter, a synchro control transformer, and in some cases a differential transmitter for additional servo inputs. The synchro transmitter transforms the motion of its shaft into electrical signals suitable for transmission to the synchro control transformer, which comprises the error detector. (See fig. 12-7.)

The stator of the transmitter consists of three coils spaced 120 electrical degrees apart.

13517

AT.235

Figure 12-7.–The control transformer as an error detector.

The voltage induced into the stator windings is a function of the transmitter rotor position. These voltages are applied to the three similar stator windings of the synchro control transformer. The voltage induced in the rotor of the synchro control transformer depends upon the relative position of this rotor with respect to the direction of the stator flux.

The variation of the synchro control transformer output voltage as a function of the rotor position relative to an assumed stator flux direction is shown in figure 12-8. While there are two positions of the rotor, 180° apart, where the output voltage is zero, only one corresponds to a stable operating position of the servo.

In cases where a synchro differential transmitter is used for additional inputs to the servosystem, it is connected between the synchro transmitter and the synchro control transformer. (See fig. 12-9.) When the synchro differential rotor is in line with its stator windings, the differential transmitter acts as a one-to-one ratio transformer and the voltages applied to the synchro control transformer are the same as the voltages from the synchro transmitter. If the synchro differential transmitter rotor is displaced by a second input, the voltages from the synchro transmitter to the control transformer are modified by the synchro differential transmitter by the amount and direction of its rotor displacement. Thus, the two inputs are algebraically added and fed to the synchro control transformer as a single input. Where a synchro differential is used as a receiver, the rotor shaft indicates the angular sum or difference between two transmitter positions.

Magnetic error detectors are not limited to E-transformers and synchro devices as other types may be encountered in equipment where special requirements must be met.

MULTIPLE-SPEED DATA TRANSMISSION SYSTEMS

The static accuracy of a servomechanism is frequently limited only by the accuracy of the data transmission system. The accuracy of the data transmission system may be increased considerably by employing a multiple-speed data transmission system along with the single-speed system. The error-detector elements of the multiple-speed transmission system rotate at some multiple of the shaft being controlled, while the elements of the single-speed transmission system operate one to one with respect to the controlled shaft.

The schematic diagram of a multiple- and single-speed system is shown in figure 12-10. If the input shaft turns through 1° in this example, the single-speed synchro transmitter also is rotated 1° while the multiple-speed unit is rotated 10°. The synchro control transformer associated with each of these transmitters is geared in similar ratios with respect to the servo output shaft. A 1° error between the position of the input and outputs shafts therefore produces a relative rotor displacement of 1° in the single-speed synchros and 10° in the multiple-

UNIT III - DRAWING GEOMETRIC CONSTRUCTIONS

Drawing a Circular Arc Tangent to Two Given Lines — Lesson 5

OBJECTIVE: To learn to draw a circular arc of any radius tangent to two given lines.

RELATED INFORMATION:

To draw a $\frac{3}{4}$-inch-radius circle tangent to two given lines AB and CD, as shown in Fig. 1: Draw a light line parallel to and $\frac{3}{4}$ inch away from each of the given lines. Where the two light lines meet at point O, place the needle point of the compass; strike an arc tangent to the two given lines. The radius for this arc will be $\frac{3}{4}$ inch.

TO CONSTRUCT A $\frac{3}{4}$-IN. RADIUS TANGENT TO TWO GIVEN LINES

FIG. 1

Application:

To draw a circular arc of $1\frac{1}{4}$-inch radius between the spokes of an idler pulley (Fig. 2), proceed as stated above. Scale any dimensions needed from the drawing shown.

APPLICATION- RADIUS BETWEEN SPOKES OF PULLEY

FIG. 2

AT.236

Figure 12-8.–Induced voltage in synchro control transformer rotor.

speed synchros. If the relation between the rotor displacement and output voltage is linear, the error signal from the multiple-speed system is 10 times that from the single-speed system. This amplification of the error signal in the data transmission link reduces the signal amplification required in the servocontroller. If the synchro has an inherent error of 0.1° with respect to its own shaft, the consequent servo error introduced by a single-speed data transmission system will be of corresponding magnitude, but the consequent servo error introduced by a 10-speed data transmission system will be only one tenth as great, or 0.01°.

A disadvantage of using a multiple-speed error detector lies in the possibility of the system falling out of step and synchronizing in a position differing from the correct position by an integral number of revolutions of the multiple-speed synchro. In the example shown in figure 12-10, if the output shaft were held fixed and the input shaft rotated 36°, the 10-speed synchro transmitter would turn one complete revolution. At this point the error signal from the multiple speed error detector would be zero. If the output shaft were then released, the system would operate in a stable fashion with a 36° error between the input and output shafts. The purpose of using a single-speed error detector along with the multiple-speed detector is to prevent this ambiguous synchronization.

An error signal selector circuit is provided which switches control of the servo to the single-speed data transmission system whenever the servo error becomes large enough to permit the multiple-speed system to synchronize falsely.

The simplest device imaginable that could control an error-selector circuit is shown in figure 12-10. It is essentially a single-pole, double-throw relay actuated by the output of the single-speed error detector. The relay is shown in the deenergized position. When the output of the single-speed synchro is high, the relay is energized and the single-speed circuit controls the servomotor. When the output is low, the relay opens and the 10-speed synchro controls the circuit. Keep in mind that the synchro output is high only when there is a large error.

The relationship of the coarse (single-speed) synchro output and the fine (10-speed) synchro output is shown in figure 12-11 (A). The shaded portion represents the area where control can be switched from single-speed circuit to the 10-speed circuit. With the selector circuit shown it is still possible to have a single ambiguous synchronizing point. This point is at the 180° position of the single-speed (coarse) synchro. At this point the single-speed (coarse) and 10-speed (fine) shafts are nulled (but are 180° out of phase) and control is switched to the 10-speed circuit.

One way of elininating this false synchronization position is to drive the multiple-speed synchro at any odd multiple of the single-speed

synchro. Figure 12-11 (B) shows the phase relationship of a single-speed and seven-speed system. Although there is still a null of both synchros at the 180° position of the single-speed synchro, their outputs are in phase. This position is an unstable one and the servo will not remain at this point.

The system illustrated in figure 12-10 is not found in operating equipment due partly to the load the relay places on the single-speed synchro. In actual practice, the relay could be controlled by an electronic circuit operated by the synchro voltages. A method commonly used feeds the outputs of the synchros to an electronic circuit biased so that the fine-synchro voltage is not used when the coarse-synchro voltage is high. This method does not require a relay.

The disadvantage of using multiple-speed error detectors is the need of an additional synchro system and switching circuit if false synchronization is to be avoided. The increased servo accuracy resulting from the amplification of the error signal and the effective reduction of inherent synchro errors account for the wide use of these multiple-speed data transmission systems.

SERVOCONTROL AMPLIFIERS

In figure 12-5, the output of the error detector (error voltage) is fed to the servocontrol amplifier. This signal is small in amplitude and requires sufficient amplification to allow actuation of the prime mover. In addition to amplification, the servocontrol amplifier must, in some cases, transfer the error signal into suitable form for controlling the servomotor or output member. It may also include provisions for special characteristics necessary to obtain stable, fast, and accurate operation.

Servoamplifiers used in aircraft armament control equipment are limited to electronic and magnetic types. The operation and explanation of electronic amplifiers and their circuits are covered in Basic Electronics.

In addition to the requirements of basic amplifiers, servoamplifiers must also meet certain additional requirements as follows:

1. A flat gain versus frequency response for a frequency well beyond the frequency range used.
2. A minimum of phase shift with a change in level of input signal. (Zero phase shift is desired but a small amount can be tolerated if constant.)
3. A low output impedance.
4. A low noise level.

Servoamplifiers may utilize either a-c or d-c amplifiers or in some instances a combination of the two. However, the application of d-c amplifiers is limited by such problems as drift and provisions for special bias voltages needed in cascaded stages. Drift, a variation in output voltage with no change in input voltage, can be caused by a change in supply voltage or a variation in value of a component. Consequently, many servoamplifiers utilize a-c amplifiers for voltage amplification. Amplifiers

are discussed further in conjunction with other circuits later in the chapter.

MODULATORS

As pointed out previously, a-c amplifiers are more satisfactory for amplifying the error signal. However, some aviation armament control equipment utilize a d-c voltage for an error signal. The d-c error voltage may be changed to an a-c signal by the use of a modulator (sometimes called a chopper). Modulator circuits used in servocontrol amplifiers must be phase sensitive and produce an a-c output signal that is proportional to the d-c input signal in amplitude and the phase of it indicative of the polarity.

Vibrator Modulators

A modulator may be either an electromechanical vibrator or an electronic circuit. An example of a vibrator is shown in figure 12-12. An a-c supply voltage is employed to vibrate the contacts of the vibrator in synchronism with the supply voltage. The d-c error voltage is applied to the center contact of the vibrator. Assume that the reference voltage will cause the center arm to contact point A during the first half cycle and point B during the second half cycle. The output is represented by waveform B if the error voltage is positive and by waveform C when the error voltage is negative.

Electronic Modulator

An example of an electronic modulator circuit is shown in figure 12-13. The input d-c error voltage is impressed between E1 and ground. The a-c reference voltage along with the action of V1, V2, R2, and R3 effectively clamp the output E2 at zero potential for onehalf cycle of the reference voltage. To accomplish this, the following conditions must exist:

1. R1 must be much larger than R2.
2. R2 and R3 are equal.
3. V1 and V2 must be matched.

With no reference voltage applied, the output E2 is the same as E1, the error voltage. With a reference voltage applied, making the plate of V2 positive and the cathode of V1 negative, current flows through V1, R2, R3, and V2. Since R2 equals R3, the voltage E3 equals E4. This effectively clamps the voltage at the junction of R2 and R3 at ground potential giving a zero output

Figure 12-12.–Vibrator modulator.

AT.241

Figure 12-13.–Electronic modulator.

AT.242

Figure 12-14.–Diode phase detector.

at E2. On the reverse half cycle V1 and V2 are nonconducting with E2 equaling E1. This results in an a-c output whose amplitude is determined by the amplitude of the d-c error signal and whose phase is determined by the polarity of the error voltage.

The examples shown above are representative of those used in aviation electronic control equipment. Variations of these circuits may be encountered. However, they all perform the same function with only slight differences in their operating principles.

PHASE DETECTORS

In the preceding section of this chapter, it has been stated that the a-c amplifier has inherent advantages over the d-c amplifier, that a d-c error voltage can be changed into an a-c signal, and the a-c signal can be amplified and applied to an a-c servomotor. However, some equipment utilize d-c servomotors which necessitates converting the a-c signal to d.c. To accomplish this, a phase detector, sometimes referred to as a demodulator, is used.

Diode Phase Detectors

A typical diode phase detector is shown in figure 12-14. As illustrated, an a-c excitation voltage serves as the reference voltage to the detector. This voltage must come from the same source that is supplying a-c excitation to the synchro system, or whatever type of error detector that is being employed, and must be in phase with the excitation voltage. This permits a phase comparison of the error voltage with the reference voltage. The plates of the two diodes are supplied with this reference voltage in such a manner that the two plate voltages are in phase. Assuming that there is no error signal from T2 to the plates of the diodes at the time the plate voltages are on a positive half cycle, the two diodes conduct equally. The voltages produced across R1 and R2 are equal, making the cathode of V1 and V2 at equal potential with respect to ground. With the two output terminals at the same potential, the output voltage remains at zero as long as there is no error signal applied.

If an error signal is applied to T2 making the plate of V1 positive at the same instant the reference voltage on the plates of V1 and V2 is on its positive half cycle, V1's conduction is increased over the no-signal condition while the voltage at the plate of V2 is decreased with a consequent reduction in conduction of V2. Since the voltages applied to the plates are both alternating, the voltage developed across R1 and R2 would also be alternating. However, R1C1 and R2C2 form a long time constant to the input frequency and filter most of the ripple, giving a d-c output.

If the error signal applied to T2 is changed by 180°, V2 would now increase its conduction while the conduction of V1 would be reduced. This would result in an output voltage of reversed polarity. Variations of the diode phase detector may be encountered; however, their principle of operation is essentially unchanged.

Triode Phase Detectors

A phase detector using triode tubes (fig. 12-15) also provides amplification of the error signal in addition to phase detection. In this circuit, as in the previous one, the plates of the tubes are supplied with the a-c reference voltage in such a manner that the plate voltages are in phase. For the purpose of explanation, assume that no error signal is present at T2. When the plates of V1 and V2 are positive, the two tubes conduct equally. The plate current that flows sets up magnetic fields in the d-c motor exciter windings that are equal and opposite; therefore, the fields cancel and produce no output. When the plate voltages are on a negative half cycle, C1 and C2 discharge through their respective exciter windings to maintain a constant direct current through the windings.

If an error signal is introduced into the primary of T2 with a phase relationship that causes the grid of V1 to be positive at the same instant that the plate of V1 is positive, the following conditions exist:

1. On this half cycle the conduction of V1 is increased above its no error signal condition.
2. The heavier plate current causes a stronger field to be created in the upper exciter winding.
3. At this same instant, since the grid of V2 is on a negative half cycle, its average conduction is reduced to a level below that of its no error signal condition.
4. The lower level of plate current causes a weaker field to be produced in the lower exciter winding.

AT.243

Figure 12-15.–Triode phase detector.

5. Since the magentic fields produced in the exciter windings are no longer of equal amplitude, they no longer cancel each other.
6. The exciter produces an output voltage of a polarity controlled by the polarity of the resultant field and of an amplitude controlled by the relative strength of this resultant field.
7. The exciter output causes the proper mechanical actions necessary to reduce the amplitude of the error to zero.
8. As the error signal is reduced to zero, the current conduction through V1 and V2 is again balanced. Also the exciter fields are equal and opposite, canceling each other, reducing the exciter output to zero, and stopping the mechanical action. Resistors R1 and R2 prevent excessive grid current when the error angle is large.

SPECIAL CIRCUITS

It has been shown how a servocontrol amplifier may have provisions for changing a d-c error signal to an a-c signal and how an a-c error signal may be detected to supply a d-c voltage to a servomotor or controller. In the following paragraphs other special amplifier circuits are discussed.

Two-Stage D-C Servocontrol Amplifier

If somewhat more power is required by the servomotor than can be supplied by the servoamplifier (fig. 12-15), a push-pull d-c amplifier can be inserted between the phase-sensitive triodes and the servomotor. In the schematic diagram (fig. 12-16), the output of the phase detector triodes is now taken across the parallel RC networks in the plate circuit.

The bias source, E_{CC}, for the d-c amplifier is connected with its positive terminal on the grid side. This positive voltage subtracts from the highly negative voltage across the capacitor to give a resulting negative voltage which allows the tube to operate on the linear portion of its characteristic curve.

When there is no signal input from the error detector, the plate currents of the phasesensitive rectifiers are equal. The outputs of V1 and V2 are applied to the grids of V3 and V4, respectively. Equal output from V1 and V2 causes equal currents to flow in V3 and V4. With R5 and R6 equal in resistance and current, the volt-

13524

AT.244

Figure 12-16.–Two-stage d-c servocontrol amplifier.

age across the motor is zero. Consequently, the motor does not turn.

When there is a signal output from the error detector, the following action occurs. Assume that the error signal makes the grid of V1 positive and the grid of V2 negative. The plate current of V1 increases and the plate current of V2 decreases. An increasing plate current in V1 increases the charge on capacitor C1 and conversely a decreasing plate current in V2 decreases the charge on capacitor C2. As a result of this change in error signal, the voltage on the grid of V3 is now more negative than the voltage on the grid of V4. This increased negative voltage on the grid of V3 decreases its plate current and the voltage e3 decreases. The decreased negative voltage on the grid of V4 increases its plate current and the voltage e4 increases. As a result, a voltage difference appears across the motor armature and the motor rotates.

When the output signal from the error detector reverses in phase, the sequence of events that follow will cause the motor to reverse its direction of rotation.

Magnetic Amplifiers as Servocontrol Amplifiers

The servomotor used in conjunction with the magnetic amplifier shown in figure 12-17 is an a-c type. The uncontrolled phase may be connected in parallel with transformer T1 by utilizing a phase shifting capacitor, or it may be connected to a different phase of a multiphase system. The controlled phase is energized by the magnetic amplifier and its phase relationship is determined by the polarity of the d-c error voltage.

The magnetic amplifier consists of a transformer (T1) and two saturable reactors, each having three windings. Note that the d-c bias current flows through a winding of each reactor and the windings are connected in series-aiding. This bias current is supplied by a d-c bias power source. A d-c error current also flows through a winding in each reactor; however, these windings are connected in series-opposing.

AT.245

Figure 12-17.–Magnetic amplifier servocontrol amplifier.

The reactors Z1 and Z2 are equally and partially saturated by the d-c bias current when no d-c error signal is applied. The reactance of Z1 and Z2 are now equal, resulting in points B and D being at equal potential. There is no current flow through the controlled phase winding.

If an error signal is applied causing the current to further saturate Z2, the reactance of its a-c winding is decreased. This current through Z1 tends to cancel the effect of the d-c bias current and increase the reactance of its a-c winding. Within the operating limits of the circuit, the change in reactance is proportional to the amplitude of the error signal. Hence, point D is now effectively connected to point C causing motor rotation. Reversing the polarity of the error signal causes the direction of rotation to reverse since point D is effectively connected to point A.

The basic magnetic servoamplifier discussed above has a response of approximately 6 to 20 hertz. In some applications this delay would be excessive, creating too much error. However, this delay can be reduced to about one hertz by using special push-pull circuits.

Amplifier Integrator

A simple and commonly used integrator consists of two circuit elements: a resistor and capacitor. (See fig. 12-18.) The voltage across the capacitor is proportional to the integral of the charging current. It can be explained by considering that the voltage across a capacitor is

$$E = \frac{Q}{C}$$

For any given capacitor (C), the voltage depends directly on the charge (Q) which is the imbalance of electrons on the two capacitor plates. The amount of this charge depends on the current flow and the time which this flow exists.

AT.246

Figure 12-18.–Simple integrator.

The fact that the voltage is proportional to the integral of the charging current allows the RC circuit to be used as an integrator. The capacitor voltage is the integrator output. Provision must be made to supply a charging current that is proportional to the input information. The purpose of the resistor is to produce this proportional current from an input signal voltage "e_i." At the instant this voltage is applied, the charging current becomes

$$i = \frac{e_i}{R}$$

Unfortunately this proportionality does not continue to exist. As the capacitor becomes charged, the capacitor voltage opposes the charging current, and the charging current becomes less proportional to the input signal. This results in an error in the output. The ideal output, for a constant input signal is a steadily increasing output. This steady increase is attained only when the signal voltage is first applied and the capacitor has not become appreciably charged.

A remedy to this error in the RC integrator is to use a circuit with a long time constant. Such a circuit delays the charging of the capacitor. The result is a more accurate integration of an input signal. The ideal output would be a perfect triangular wave. Although a long time constant produces more accurate results, it also provides a much lower output for the same input signal. Better integration is possible by the use of a high gain, feedback amplifier.

An amplifier integrator is illustrated in figure 12-19. This circuit arrangement uses a high gain amplifier and is known as the Miller integrator. The amplifier produces an output which is not limited by the input signal as it is in the simple RC integrator. The amplifier also supplies any energy which is required in the output. The function of the input signal is to control the charging current.

The operation can be explained by assuming a constant input as shown in figure 12-19 (A). At the start, assume the initial condition is zero, that is,

$$e_i = e_g = e_o = 0$$

13526

AT.247

Figure 12-19.–Amplifier integrator.

Also assume that the capacitor is discharged. The positive voltage to be integrated, "e_i," is then applied. The capacitor charges with a polarity as shown, since electrons are attracted from the left plate. The charging path is shown in figure 12-19 (B).

A voltage measured at the amplifier input, "e_g," tends to rise in the positive direction since this point is directly coupled to "e_i," However, this rise tends to be opposed by the degenerative feedback voltage from the output. The output will be $-Ae_g$ (e_o). The letter "A" stands for the amplifier gain. The minus sign indicates that the out polarity or phase is opposite to the input. The output changes "A" times faster or steeper than "e_g." The output voltage is negative and aids the charging of the capacitor.

For a certain input voltage, the charging current is limited to a particular value which tends to keep "e_g" practically zero. If the current should exceed this value, "e_g" would decrease a small amount due to the increased voltage drop across R. Then e_o would decrease, and the charging current would decrease to the original value. If the initial charging current should decrease, the opposite action would occur. The value of the charging current is therefore stabilized to a specific value proportional to the input voltage. This eliminates the error caused by "e_i" and the charging current not remaining proportional in the fundamental RC integrator.

This constant charging current must be produced by "e_o" despite the fact that the steadily increasing capacitor voltage opposes the charging current. To do this, "e_o" must also steadily increase. This steady increase in "e_o" is exactly the integrator output voltage desired for a constant signal input.

Similar action would be produced for a condition in which the input signal suddenly became negative. Polarities then would be in reverse to those shown in the example given. Remember that simple examples are used for explanation on the assumption that the desired result also will be produced for a more complicated signal input. Removal of "e_i" would produce little effect upon the the output which existed at that instant, since the amplifier output would oppose the tendency for the capacitor to discharge.

The limits for "e_o" are determined by the amplifier and not by "e_i" or the range of "e_g." The output range would be designed to produce an increasing output for any probable input amplitude and period of application. The exception to this would be an integrator which was designed to function also as a limiter.

OUTPUT DEVICES

The output of the servocontrol amplifier is fed to an output device. The functions of this device, usually a servomotor, are to supply torque, power, and dynamic characteristics required to position the servo load. Ideally, the power device should require small power from the control amplifier, accelerate rapidly, be of small size and weight, be of lasting endurance, have small time lags, and have an adequate speed range. In aviation electronic systems, the electric motor is most frequently used as an output device.

ELECTRIC MOTORS

In aviation electronic equipment, electric motors are primarily used to drive the servo

39527

load. The type of electric motor used within a particular equipment is determined by such factors as type of power available, output power, speed range, inertia, and electrical noise.

Alternating-Current Motors

Alternating-current motors are frequently used in low power servo applications because of their simplicity, reliability, absence of commutator sparking, and rapid response. However, they have a disadvantage of having a narrow speed range characteristic. The theory of operation of a-c motors is discussed in Basic Electricity. However, this training manual briefly discusses the types of motors applicable to servosystems.

The 2-phase induction motor is the most widely used a-c servomotor. The stator of the motor consists of two similar windings which are positioned at right angles to each other. The rotor may be wound with short-circuited turns of wire or it may be a squirrel cage rotor. The squirrel cage rotor is the type most frequently encountered. It is made up of heavy conducting bars which are set into armature slots, the bars being shorted by conducting rings at the ends.

Two a-c voltages 90° out of phase must be applied to the stator windings in order for the motor to turn. These out-of-phase voltages generate a rotating magnetic field which induces a voltage in the rotor. This induced voltage generates a magnetic field in the rotor that is displaced 90° from the stator magnetic field. The interaction of the two magnetic fields causes the armature to rotate.

As stated previously, the voltage to the two stator windings must be 90° out of phase to cause the rotor to turn. The direction of rotation is determined by the phase relationship of the stator windings which, in turn, is determined by the servo error detector. One phase is connected directly to one of the stator windings while the other phase is used to energize an error detector. The resulting error voltage is either in phase or 180° out of phase with the signal applied to the error detector. This will cause the controlled phase to either lead or lag the uncontrolled phase by 90°.

Most induction motors have low starting torque and high torque at high speed. For servo applications, it is desirable to have high starting torque in order that the system may have a low time lag. This may be accomplished by increasing the armature resistance with the use of materials such as zinc for the conducting bars. This increased torque at low speed results in decreased torque at high speed. However, increased stability of the servosystem is a desirable result of this change.

Split-phase a-c motors are similar to the 2-phase induction motor. It differs only in that a phase shifting network is used to shift the phase of the voltage supplied to one of the windings by 90°. This is usually accomplished by connecting a capacitor in series with the uncontrolled winding of the stator. Direction of rotation and reversal is accomplished in the same manner as in the 2-phase motor discussed above.

Other types of motors that may be used with an a-c power supply are shaded pole, universal, and repulsion motors. They utilize various methods of obtaining rotation reversal.

Direct-Current Motors

Direct-current motors have an advantage of having higher starting torque, reversing torque, and less weight for equal power than a-c motors.

Series motors are characterized by their high starting torque and poor speed regulation with a change in torque. Higher torque can be obtained on reversal of direction with a series motor than any other type. However, it is a unidirectional motor and requires special switching circuits to obtain bidirectional characteristics. This is normally done by switching either the armature or field connections but not both.

A variation of the series motor that has bidirectional characteristics is the split-series motor. The motor has two field windings on its frame, only one of which is used for each direction of rotation. This reduces the number of relay contacts required for reversing by one-half. This double winding also reduces the torque capabilities of the motor as compared to a straight-series motor wound on the same frame.

The most frequently used d-c servomotor is the shunt motor. Its direction of motion is controlled by varying the direction of flow of either the armature or field current. The uncontrolled current is usually maintained constant to preserve a linear relationship between the motor output torque and the voltage or cur-

UNIT III - DRAWING GEOMETRIC CONSTRUCTIONS

Constructing an Approximate Ellipse by the Four-Center Method — Lesson 6

OBJECTIVE: To learn the four-center method of approximating an ellipse.

RELATED INFORMATION:

TO CONSTRUCT AN APPROXIMATE ELLIPSE BY THE FOUR CENTER METHOD

FIG. 1

To draw an approximate ellipse through the given points A, D, and B by the four-center method (Fig. 1): Draw the major axis AB and the minor axis CD as shown. Let the minor axis equal approximately one-half the major axis. Note: The minor axis may be any length, so long as it is smaller than the major axis. Draw line AD. With O as a center and radius OA, scribe arc AE. With D as a center and radius DE, scribe arc EF. Bisect line AF. Where the bisector of line AF meets the extension of the minor axis at point G, we have the center for the arc HDI. Step off distance OJ equal to OG and OL equal to OK. Draw lines from point J through K and L. With J as a center and a radius equal to JC, scribe arc MCN. Complete the ellipse with K and L as centers and radii equal to KA and LB respectively.

Application:

To construct the front view of an angle support (Fig. 2), proceed as stated above. Scale any dimensions needed from the drawing shown.

APPLICATION - ANGLE SUPPORT

FIG. 2

135

rent input. The field windings are usually two differentially wound coils to facilitate direction control of the field current by the servocontrol amplifier. The field current is usually controlled with receiving type vacuum tubes. The larger armature currents require thyratrons or generators as current regulators.

MAGNETIC CLUTCHES

Any device utilizing an electrical signal that may be used to control the coupling of torque from an input shaft to an output shaft is a magnetic clutch. This coupling may be accomplished by the contact between friction surfaces or by the action of one or more magnetic fields. A magnetic clutch is used only to couple the input torque to the output shaft. Thus, it is capable of controlling large amounts of power and torque for its size and weight. The magnetic clutch may be used with a large flywheel driven at high speed by a small motor. This allows the flywheel to impart very large acceleration to the load when the magnetic clutch is energized.

There are two distinct types of magnetic clutches. Some transmit torque by physical contact of frictional surfaces. Others utilize the action of magnetic flux produced by two sets of coils or one set of coils and induced eddy currents resulting from rotating the one set of coils near a conducting surface. The eddy current type of clutch offers smoother operation and has no problem of wear due to friction. Both types have suitable control characteristics and are found in servomechanisms.

HYDRAULIC DEVICES

Hydraulic components used in servomechanisms are frequently found in aviation electronic equipments such as radar antennas. Hydraulic power devices, such as motors and associated control valves, have an advantage of a response much faster than the best electric motors and equal to that of a magnetic clutch system. They also require a minimum of maintenance, have very high accuracy, and are well adapted to heavy loads.

The essential components of a hydraulic system are:

1. Source of high pressure oil and sump to receive discharged oil.
2. Control valve and means of employing an actuating signal.
3. Actuator (motor or cylinder).

The theory of operation of a hydraulic system is discussed in Fluid Power, NavPers 16193-A.

The source of high pressure oil serves as a source of power to operate the actuator. However, this source of power is controlled by the control valve. This valve is actuated by the output from the servocontrol amplifier. This control is normally accomplished by feeding the error signal to a solenoid controlled valve. However, the error signal could be used to drive an electric motor which, in turn, actuates the control valve. The actuator is usually in the form of an axial motor which must be a reversible and variable speed type. Some applications may employ a cylinder where linear motion is required for positioning.

SERVOMECHANISM OSCILLATION

Servomechanisms are utilized for various functions and must meet certain performance requirements. These requirements not only concern such things as speed of response and accuracy, but the manner in which the system responds in carrying out its command function. All systems contain certain errors, the problem being to keep them within the allowable limits.

As discussed previously, the servomotor must be capable of developing sufficient torque and power to position the load in a minimum of time. The servomotor and its connected load have sufficient inertia to drive the load past the point of command position. This overshooting results in an opposite error voltage, reversing the direction of rotation of the servomotor and the load. The servomotor again attempts to correct the error and again overshoots the point of correspondence with each reversal requiring less correction until the system is in correspondence. The time required for the oscillations to die out determines the transient response of the system and can be greatly reduced by the use of damping.

DAMPING

The function of damping is to reduce the amplitude and duration of the oscillations that may exist in the system. The simplest form of

13529

damping is viscous damping. Viscous damping is the application of friction to the output load or shaft that is proportional to the output velocity. The amount of friction applied to the system is critical and will materially affect the results of the system. When just enough friction to prevent overshoot is applied, the system is said to be critically damped. When the friction is greater than that for critical damping, the system is overdamped. However, when damping is slightly less than critical, the system is said to be slightly underdamped, which is usually the desired condition. The application of friction absorbs power from the motor and is dissipated in the form of heat.

A pure viscous damper would absorb an excessive amount of power from the system. However, a system having some of the characteristics of a viscous damper with somewhat less power loss is used in actual practice. The first of this type of damper to be discussed utilizes a dry friction clutch to couple a weighted flywheel to the output drive shaft. A flywheel has the property of inertia which may be defined as that property of matter by which it will remain at rest or in uniform motion in the same straight line or direction unless acted upon by some external force.

However, since the flywheel is coupled to the output shaft with a friction clutch, any rapid change in velocity of the output member causes the clutch to slip. This slipping effectively disconnects the flywheel instantaneously but allows sufficient power to be coupled to the flywheel to overcome its inertia. As the inertia is gradually overcome, the flywheel gains speed and approaches the velocity of the output member. As the point of correspondence is neared and the error signal is reduced, the inertia of the flywheel gives up power to the system, causing the load to increase its overshoot. When the system attempts to correct for this overshoot, the inertia of the flywheel adds to the output load, reducing the effect of the correcting signal. This effect dampens the oscillations in the system, reducing its transit time.

Another type of damper used is the eddy current damper. This damper utilizes the interaction of induced eddy currents and a permanent magnet field to couple the output shaft to a weighted flywheel.

The effect of damping is shown in figure 12-20. The soild line shows the action of the load without damping. The time required to reach a steady-state condition without damping should be noted. This time is greatly reduced although the initial overshoot is increased.

As shown in figure 12-20, viscous dampers effectively reduced transient oscillations, but it also produced an undesired steady-state error (velocity lag or position error). Since the friction damper absorbs power from the system, its use is normally limited to small servomechanisms.

To overcome the disadvantages of the viscous dampers and still provide damping, error-rate damping is used. This type of damping consists of introducing a voltage that is proportional to the rate of change of the error signal. This voltage is fed to the servocontrol amplifier and combined with the error signal. Figure 12-21 shows the effect of error-rate damping on the torque output of the servomotor. Curve A shows the torque resulting from the error voltage; curve B shows the torque resulting from the error-rate damper; and curve C depicts the resultant of curves A and B. It should be noted that torque resulting from the damper increases the total torque as long as the error component is increasing. Once the error component starts to decrease, the error-rate damper produces a torque in an opposite direction reducing the transit time of the system.

There are two methods of generating an error-rate voltage normally found in aviation

AT.248

Figure 12-20.–Effect of friction damper.

13530

AT.249

Figure 12-21.–Torque variations using error-rate damping.

electronic equipments. They are the tachometer and electrical networks. The tachometer error-rate damper utilizes a device which is essentially a generator having an output voltage proportional to its shaft speed. The tachometer is connected to the shaft of the output member giving a voltage proportional to its speed. The output voltage is fed to a network that modifies this voltage so that it is proportional to a change in input voltage. This voltage is fed back to the servocontrol amplifier and added with the error signal as shown in figure 12-21.

Electrical networks used for error-rate damping consist of a combination of resistors and capacitors used to form an RC differentiating network. For a detailed explanation of RC circuits, refer to Basic Electricity. These networks, sometimes referred to as phase advance or lead networks, vary in design, depending on the type of error signal. However, in practice, networks are normally limited to the d-c type. (See fig. 12-22.) This is because of the unstable results that would be caused by a small change in frequency of the power source. An a-c system may utilize a d-c network by first using a demodulator (detector) prior to the network. However, the output of the network must be modulated for use in the remainder of the a-c system. Like the tachometer, the output of the network is fed to the servocontrol amplifier.

AT.250

Figure 12-22.–Error-rate stabilization network.

INTEGRAL CONTROL

Servomechanisms used in electronic equipment are sometimes required to follow an input function, the magnitude of which changes at a constant rate with time. Thus, if the input is the angle of a shaft, the velocity of the shaft may be constant for a substantial percentage of time. The servomechanism may be required to respond to this type of input with substantially zero error. The error that characterizes the servo response to a constant velocity input is known as the velocity error.

To correct for velocity error or an inaccuracy due to a steady-state error, an integral control may be used. This control modifies the error voltage in such a manner that the signal fed to the servocontrol amplifier is a function of both the amplitude and time duration of the error signal. This is accomplished by the use of a variable voltage divider whose output would increase with time for a constant input. As in all voltage dividers, the output is only a portion of the input which effectively reduces the amplitude of the error signal. To compensate for this loss of amplitude, additional amplification must be used either in the form of a preamplifier or a higher gain servocontrol amplifier. With the overall gain of the system now increased to give a normal output for transient error signals, small velocity or steady-state error signals of long duration will result in somewhat increased output to the servomotor due to the action of the integral control.

The integral control (fig. 12-23) consists of a combination of resistors and capacitors connected to make an integrator circuit for a d-c error signal. The value of the components are such that the capacitor does not have sufficient

time to change with fluctuations in error voltage. Only that portion of the transient error signal developed across R1 is impressed on the amplifier. However, with a velocity error or steady-state error of longer duration, the capacitor (C1) charges, increasing the amplitude of the amplifier input.

Networks shown in figure 12-23 are not limited to d-c systems as a demodulator may be used prior to the integrator and its output modulated for easier amplification.

GAIN, PHASE, AND BALANCE

The overall system gain has a most important effect on the servomechanism response characteristics and is one of the more easily adjustable parameters in electronics servocontrollers. Increasing the system gain reduces the system velocity errors and those steady-state errors resulting from restraining torques on the servo load or misalinement in the system. An increase in system gain also increases the speed of response to transient inputs. However, excessive gain always decreases the rate at which oscillatory transients disappear, and continue increase in the system gain eventually produces instability.

Servosystems using push-pull amplifiers must be balanced to insure equal torque in both directions of the servomotor. This adjustment should be checked periodically as a change in value of a component may cause an unbalanced output. Balancing is accomplished by adjusting the system for zero output with no signal applied.

A phase control is included in some servosystems using a-c motors. The two windings of the a-c servomotor must be energized by a-c signals that are 90° apart. A phasing adjustment is normally included in the system to compensate for any phase shift in the amplifier circuit resulting in unstable operation of the system. This adjustment may be located in the control amplifier, or in the case of a split-phase motor, it may be in the uncontrolled winding.

ZEROING SYNCHRO UNITS

In this chapter the importance of accuracy of servomechanisms has been stressed. In any servomechanism using synchro units, it is also very important that the units be zeroed electrically.

For a synchro transmitter or receiver to be in a position of electrical zero, the rotor must be alined with S2, the voltage between S1 and S3, as shown in figure 12-24 (A), must be zero, and the phase of the voltage at S2 must be the same as the phase of the voltage at R1.

TRANSMITTERS AND RECEIVERS

The most common methods of zeroing synchro transmitters and receivers are the a-c voltmeter method and the electrical lock method. The method used to zero a synchro depends upon how the synchro is used. Where the rotor is free to turn the electrical lock method can be used. This is accomplished by connecting S1 and S3 to R2 using a jumper wire and connecting S2 to R1. (See fig. 12-25.) When power is applied, the rotor will position itself in the zero position. After the synchro is zeroed, the pointer is adjusted to indicate zero.

Possibly the great majority of synchros used in aviation electronic equipment have their rotors gear driven or mechanically coupled to a driving member. In these cases it is necessary to use the a-c voltmeter method, zeroing the synchro by rotating the stator or housing until its electrical zero is reached. Before zeroing the synchro, the mechanical unit that positions the synchro must be set to its indexing or ZERO position. This is done by alining the unit to its index and installing its indexing pins in the holes provided for this purpose. The pins hold the unit to its index and keep it from moving.

The a-c voltmeter method is done by connecting the meter and jumper wires as shown in (A) of figure 12-26. Rotate the energized synchro

195

AT.252

Figure 12-24.–Synchro electrical zero positions.

until a zero reading is obtained on the voltmeter. Since rotor positions of zero degree and 180° produce this zero reading, it is necessary to determine if the phase of S2 is the same as that of R1. Make the connections as shown in (B) figure 12-26. If the proper polarity relationship exists, the voltmeter indicates less than the excitation voltage being applied to the rotor. If the indication is greater than the rotor excitation voltage, the rotor (or stator) must be rotated 180° and the previous step must be performed again.

The electrical zero position of a synchro differential transmitter or receiver is when the three windings of the rotor are in correspondence with their respective stator windings and their respective voltages are in phase. (See fig. 12-24 (B).)

Because the differential transmitter synchro is normally used to insert a correction into a synchro system, it is usually driven either directly or through a gear train. Before zeroing the differential transmitter synchro, the unit whose position the differential synchro transmits should first be zeroed. After this has been accomplished, connect the differential synchro as shown in figure 12-27 (A). Turn the synchro in its mounting until the voltmeter shows a minimum indication. After completing this step, make the connections shown in figure 12-27 (B). Again turn the synchro slightly in its mounting, until a minimum voltage is indicated by the voltmeter.

AT.253

Figure 12-25.–Electrical lock method of zeroing a synchro.

Electrical zero for a differential receiver is illustrated in figure 12-24 (B). To zero a differential receiver synchro, make the connections shown in figure 12-28. As soon as the power is applied to the synchro, the rotor assumes a position of electrical zero. The dial can be set at zero and the unit reconnected to its circuit.

The synchro control transformer is normally zeroed by using the a-c voltmeter method. It should be remembered that the electrical zero position of the control transformer is 90° from that of a receiver since the rotor winding must be perpendicular to the stator's resulting magnetic field to have a zero output. (See fig. 12-24 (C).) The coarse adjustment is made by connecting the meter and unit as shown in figure 12-29(A). The rotor is rotated to give a minimum or null reading on the voltmeter. The final adjustment is made by connecting the unit as shown in figure 12-29 (B) and displacing the rotor a few degrees in both directions to determine the null or electrical zero position. Once the

Figure 12-26.–A-c voltmeter method of electrically zeroing synchro receiver or transmitter.

Figure 12-28.–Electrically zeroing a differential synchro receiver.

2838534

zero position has been determined, the unit must be locked as discussed previously.

SYNCHRO ALIGNMENT SET TS-714/U

The Synchro Alignment Set TS-714/U (fig. 12-30) is a portable, general purpose test set used to check the alinement of synchros or resolvers. It can be used to aline any 400-Hz synchro or resolver. In addition to its higher sensitivity, the test set has an additional advantage over the methods previously discussed in that the test set can also supply excitation voltage for the synchro or resolver being alined.

The test set basically consists of a bandpass amplifier and power supply, a synchro or resolver excitation supply with outputs from 3 to 115 volts rms (selected by switch 1 of fig. 12-30) and switching circuits. The output voltages from the synchros or resolvers are applied to the amplifier, the output of which is fed to a phase sensitive detector circuit. The detector's output is metered by the microammeter (2 of fig. 12-30). A meter switch (3) selects the meter sensitivity from 300 volts full scale to 0.1 volt full scale; it also has a calibrate position and an off position.

AT.257

Figure 12-29.–Electrically zeroing a control transformer synchro.

The meter has a zero-center scale and indicates zero when the synchro or resolver is adjusted to either of its two nulls. The synchro or resolver is adjusted to a null position with the function switch (4) in the ZERO position. When the null is reached, the function switch is switched to the POL position and note is taken of the meter reading. Then the function switch is returned to ZERO position and the synchro is rotated 180° to its opposite null. When the opposite null is reached, the function switch is again switched to the POL position and a note made of the reading. The correct null will be the one indicating the lowest reading with the function switch in the POL position. When the synchro is adjusted to this null, it is electrically zeroed with the correct polarity.

For detailed instructions on the use of the TS-714/U, consult Operation and Service Instruction Manual, NA 11-70-FAG-510.

Typical Application

A practical application of a complete servosystem is found in the antenna tilt stabilization circuits of radar systems. Tilt stabilization is used to tilt the angle of the transmitted beam of RF energy to compensate for deviations in the attitude of the aircraft. Throughout the scanning azimuth of the antenna, the beam is maintained at the angle selected by the operator. The selected angle is set by the tilt control on the radar antenna control unit.

The stabilization range on one type of radar is such that if the tilt control is set for 0°, the beam is maintained at this angle for aircraft pitch or roll angles up to -30°. If the tilt control is set for other beam angles, these limits will vary accordingly. A typical tilt stabilization system is illustrated in figure 12-31.

The conditions of flight assumed for reference result in the waveforms shown at the left of the figure. These conditions are as follows:

1. Aircraft is entering a climb.
2. Manual tilt control is set for zero tilt.
3. Tilt stabilizer mechanism is functioning in response to gyro signals.
4. Scanner's instantaneous position is "dead ahead."

NOTE: The amplitude for waveforms 7 and 8 are not drawn to comparative scale.

The tilt stabilization system, shown in figure 12-31 consists of a gyroscope unit, a servoamplifier, the resolver synchro, manual tilt synchro, tilt torque motor, damping signal gengenerator, and followup synchro. The gyroscope unit is separately mounted on the aircraft structure, and the resolver synchro and the servoamplifier are mounted on the antenna frame. The tilt torque motor, damping signal generator, and followup synchros are contained in the tilt servo unit mounted on the rotary section of the antenna. The manual tilt synchro is mounted on the antenna control box.

Stabilization is effected by the use of two signals—the resolver synchro signal, and the manual tilt synchro signal. Separate pitch and roll signals originating in the gyroscope unit are combined in the resolver synchro to produce the single resolver synchro signal. The manual tilt synchro signal originates in the followup synchro and provides the tilt stabilization system with continuous information as to the tilt angle of the reflector. This signal passes through the manual tilt synchro in the antenna control where it is modified according to the setting of the tilt control. The resolver synchro signal and the manual tilt synchro signal differ in phase by 180°. They are combined at the input of the servoamplifier. The amplifier resultant, or error signal, is used to control the tilt torque motor, which corrects the tilt angle of the reflector.

Learning the Alphabet of Lines — Lesson 1

OBJECTIVE: To learn the different types of lines used in the field of drafting.

ALPHABET OF LINES

FIG. 1

RELATED INFORMATION:

1. Object lines. - These lines describe the shape of the object and are generally heavier than other lines. They must be of uniform weight and should not thin out near their ends.

1359

CHAPTER 13

ELECTRONIC MAINTENANCE, PART I

The purpose of this chapter is to set forth general maintenance procedures rather than the detailed procedures used with specific units and sets; however, for purposes of illustration, specific electronic units and sets are mentioned. Discussion is given to the troubleshooting procedures used in aircraft as well as on the bench, and repair information concerning electronic circuit construction, replacement of parts, electrical connectors, cables, and terminal blocks.

TROUBLESHOOTING

Much of the technician's time is spent troubleshooting the equipment in the squadron's aircraft. The technician's job is to maintain a great number of units and systems, many of which are quite complex, and which might seem at a glance beyond his ability to maintain. However, the most complex job usually becomes much simpler if it is first broken into successive steps. Any maintenance job should be performed in the following order:

1. Analyze the symptom.
2. Detect and isolate the trouble.
3. Correct the trouble and test the work.

AIRCRAFT PROCEDURES

In troubleshooting, as in most other things, there is no substitute for commonsense. A mistake made by most beginners is to remove major units from the aircraft unnecessarily. When a "squawk" is received, the first step is to determine if the equipment in question is actually faulty. Very often a preliminary check of the system in the aircraft will disclose a faulty control box, frayed or broken wiring, corroded or wet connectors, and, in rare cases, improper operating procedure—especially with new equipment. (Improper operating procedures are especially common when the reported discrepancy involves new equipment or personnel undergoing indoctrination.)

If there is no power present at the input to the equipment, it may be assumed (temporarily) that the set is not defective. Check all applicable switch positions, circuit breakers, fuses, etc., then check for power at the bus which feeds the equipment. Check the tightness and the physical condition of interconnecting cables. Using the wiring diagrams in the applicable manuals, check at successive tie points and splices for continuity, short circuits, or grounds. The procedures to be followed with these tests are discussed later in this chapter under the heading Basic Tests.

If a circuit breaker is tripped or if a fuse is blown, a circuit malfunction is indicated. Power to the circuit containing the "open" should be turned off, and should not be reapplied until the malfunction is located and corrected. The most common causes of tripped or blown circuit protectors are short circuits, faulty grounds, or overload conditions. However, circuit protectors sometimes fail due simply to age or to transient conditions. If, after a thorough check, no apparent reason for the failure can be found, the breaker may be reset or the fuse replaced with the proper size and type, and the power reapplied. If the protector fails again, a malfunction is definitely indicated.

If the analysis does not indicate the existence of a short circuit, faulty ground, or overload condition, but the equipment still does not operate, continue to take measurements with power applied. These measurements should be taken systematically at progressive checkpoints. Particular faults which may interrupt current

13538

through a circuit include broken wiring, loose or faulty terminal or plug connections, faulty relays or switches, and uncoupled splices. Be alert for these conditions.

If the defective unit cannot be identified while still installed in the aircraft, it may be advisable to turn off the power and substitute units, one at a time with units which are known to operate properly. As each unit is replaced, power should be reapplied and the system checked for operation or for symptoms of nonoperation. If the system operated normally, the faulty unit has been identified, and the faulty unit may be taken to the shop for corrective maintenance. At this stage of the overall maintenance process, it is also advisable to try to determine the reason for the failure of the unit–it is conceivable that the new unit may also be damaged if the basic cause is not corrected.

Following removal of the defective unit and the subsequent analysis, all other items of the original installation should be reinstalled and safety wired, and an operational check performed. During the operational check, any readjustments or calibrations should be accomplished as required. This should be done prior to clearing the discrepancy on the Maintenance Action Form.

Basic Tests

Several rules are set forth below and are intended as a guide to follow when making the tests described in this section.

1. Always connect an ammeter in series.
2. Always connect a voltmeter in parallel.
3. Never connect an ohmmeter to an energized circuit.
4. Select the highest range first then switch to lower ranges as needed.
5. When using an ohmmeter, select a scale that will result in a midscale reading.
6. Do not leave the selector switch of a multimeter in the resistance position when the meter is not in use because the leads may short together and discharge the internal battery. There is less chance of damaging the meter if it is left on a high a-c volts setting or in the off position if it has one. Meters that have an off position dampen the swing of the needle by connecting the meter movement as a generator. This prevents the needle from swinging wildly when the meter is moved.
7. View the meter from directly in front to eliminate parallax.
8. Observe polarity when measuring d-c voltage or direct current.
9. Do not place meters in the presence of strong magnetic fields.
10. Never attempt to measure the resistance of a meter or a circuit with a meter in it as the high current required for ohmmeter operation may damage the meter. This also applies to circuits with low-filament current tubes and some types of semiconductors.
11. When measuring high resistance, be careful not to touch the test lead tips or the circuit as body resistance will shunt the circuit and give an erroneous reading.
12. Connect the ground lead of the meter first when making voltage measurements. Work with one hand whenever possible.

CONTINUITY TEST.–Open circuits are those in which the flow of current is interrupted by a broken wire, defective switch, or any means by which the current cannot flow. The test used to check for opens (or to see if the circuit is complete or continuous) is called continuity testing.

An ohmmeter (which contains its own batteries) is excellent for a continuity test. In an emergency, a continuity tester can readily be made from a flashlight. Normally, continuity tests are performed in circuits where the resistance is very low (such as the resistance of a copper conductor). An open circuit is indicated by a very high or infinite resistance. Such a condition would be an open conductor.

The diagram in figure 13-1 shows a continuity test of a cable. Notice that both connectors are disconnected and the ohmmeter is in series with the conductor under test. The power must be off. Checking conductors A, B, and C, the current from the ohmmeter will flow through plug No. 2, through the conductor, and plug No. 1. From this plug it will pass through the jumper to the chassis which is "grounded" to the aircraft's structure. The structure will serve as the return path to the chassis of unit 2 completing the circuit to the ohmmeter. The ohmmeter will indicate a low resistance.

13539

Checking conductor D (fig. 13-1) will reveal an open. The ohmmeter will indicate maximum resistance because current cannot flow. With an open circuit, the ohmmeter needle is all the way to the left since it is a series type ohmmeter (reads right to left).

Where conditions exist that the aircraft structure cannot be used as the return path, one of the other conductors may be used. For example, to check D (fig. 13-1) a jumper is connected from pin D to pin A of plug 1 and the ohmmeter leads are connected to pins D and A of plug 2. This technique by the process of elimination will also reveal the open in the circuit.

GROUNDED CIRCUIT TEST.–Grounded circuits are caused by some conducting part of the circuit making contact either directly or indirectly with the metallic framework of the aircraft. Grounds may have many causes, the most common of which is perhaps the fraying of insulation from a wire allowing the bare wire to come in contact with the metal ground.

Grounds are usually indicated by blown fuses or tripped circuit breakers. Blown fuses or tripped circuit breakers, however, may also result from a short other than ground. A high resistance ground may also occur where sufficient current does not flow to rupture the fuse or open the circuit breaker.

In testing for grounds, the ohmmeter is used. Other continuity testers may also be used. By measuring the resistance to ground of any point in a circuit, it is possible to determine if the point is grounded. By considering figure 13-1, one possible means of testing a cable for grounds can be seen. If the jumper is removed from pin D of plug No. 1, a test for grounds is made for each conductor of the cable. This is accomplished by connecting one meter lead to ground and the other to each of the pins of one of the plugs. A low resistance will indicate that a pin is grounded. Both plugs must be removed from their units; if only one plug is removed, a false indication is possible for a conductor may be grounded through the unit.

SHORT TEST.–A short circuit, other than a grounded one, is one where two conductors accidentally touch each other directly or through another conducting element. Two conductors with frayed insulation may touch and cause a short. Too much solder on the pin of a connector may short to the adjacent pin. In a short circuit, sufficient current may flow to blow a fuse or open a circuit breaker. However, it is entirely possible to have a short between two cables carrying signals; such a short will not be indicated by a blown fuse.

Figure 13-1.–Continuity test.

As when checking for a ground, the device used for checking for a short is the ohmmeter. By measuring the resistance between two conductors a short between them may be detected by a low resistance reading. In figure 13-1 by removing the jumper and disconnecting both plugs, a short test may be made. This is performed by measuring the resistance between the two suspected conductors.

Shorts are not reserved for cables, they occur in many components, such as transformers, motor windings, capacitors, etc. The major test method for testing such components is a resistance measurement, and then comparing the indicated resistance with the resistance given on schematics or in maintenance manuals.

VOLTAGE TEST.–The voltage test must be made with the power applied; therefore, the prescribed safety precautions must be followed to prevent injury to personnel and damage to the equipment. The technician will find in his maintenance work that the voltage test is of utmost importance. It is used not only in isolating casualties to major components but also in the maintenance of subassemblies, units, and circuits. Before checking a circuit voltage, a check on the voltage of the power source should be made to be sure that the normal voltage is being impressed across the circuit.

BENCH PROCEDURES

The visible condition of a unit is usually the first thing to check in any process of troubleshooting. If certain parts are obviously not in proper condition, these faults must be corrected before going any further in the tests. Such conditions include parts which are burned, loose from their mountings, disconnected, dented, broken, or otherwise obviously faulty. This step should be accomplished prior to installing and connecting the unit at the test bench.

The sense of smell can be helpful in pinpointing certain troubles. A part that overheats usually gives off an odor that is readily detectable, and can sometimes be located by the odor given off. However, location of a burned part does not necessarily reveal the cause of the trouble.

In determining the cause of the trouble it is usually necessary to refer to the Service Instruction Manual. This manual will be a valuable source for constant reference when performing maintenance on electronic equipment. Few technicians are so thoroughly familiar with an electronic unit that they do not have to use the manual when performing maintenance. Chapter 4 of this training manual contains a detailed description of the information that is presented in the Service Instruction Manuals.

Signal Tracing

The following procedure is given for tracing signals in RF receivers and audio amplifiers; however, this general procedure, with modifications, can be applied to most electronic troubleshooting. In radar the frequencies are higher, the methods of signal application differ, and the output in the final stage is video (veiwed) on a scope, instead of audio (heard) from a speaker or headset. The applicable Service Instruction Manual contains detailed procedures for testing most units or circuits.

Signal tracing is a very effective method for locating defective stages in many types of electronic sets. It is especially useful when servicing sonobuoy receivers, audio amplifiers, and other equipment which normally contain no built-in meters. In signal tracing, a signal voltage (similar to that which is present under operating conditions) is taken from a signal generator and is then applied to the input of the circuit in question. The signals which result are then checked at various points in the stage, using test instruments such as vacuum tube voltmeters, oscilloscopes, output meters, or any high impedance instrument which is appropriate. (The test instrument should have high impedance so that it will not change the operation of the circuit to which it is applied.)

When using the signal tracing technique to measure a-c signals, be sure that the test instruments are adequately isolated from any d-c potentials present in the circuit. Some test instruments are equipped with special a-c probes which incorporates a capacitor in series with the input; other equipments are not so equipped. Before using any item of test equipment, the technician must familiarize himself with the characteristics and proper use of the test equipment, as well as with the equipment under test.

13541

13240

By signal tracing methods, the gain or loss of amplifiers can be measured; and the points of origin of distortion and hum, noise, oscillation, or any abnormal effect can be localized.

The gain measurement can be used as an example of an important method in signal tracing. By this procedure, a defective stage can be found quickly in a radio sonobuoy receiver or audio amplifiers. A signal generator, with the output attenuator calibrated in microvolts, and an output meter are used. It is helpful to have data concerning the normal gain of the various stages of the device. These data are generally found in the Service Instruction Manual for the receiver under test.

The output meter may be connected across the headset (or the voice coil of a speaker) or across the secondary of the output transformer. The output of the signal generator is applied to the grid circuit of the stage under test. The attenuator of the signal generator is then adjusted until the output meter reads a value appropriate to serve as a reference figure. The output of the signal generator is then applied to the output of the stage under test (or to the input of the next stage), and the attenuator is adjusted until the same reference value is again registered on the output meter. The gain of the stage is found by dividing the second value of the signal (taken from the calibrated attenuator) by the value of the signal applied to the input of the stage.

As an example, suppose the signal generator supplies a voltage of 400 microvolts to the grid of an IF amplifier. This voltage causes the output meter to indicate some value that can be used as a reference. When the generator signal is applied to the following grid, the signal strength must be increased (to 4,000 microvolts) to cause the output meter to indicate the same reference value. The gain of the stage is equal to

$$\frac{E_{in}\ \text{2nd stage;}}{E_{in}\ \text{1st stage}} \quad \text{that is,} \quad \frac{4{,}000}{400} = 10$$

If similar measurements made in the remaining stages of the receiver reveal one stage in which the gain is lower than normal or is zero, that stage can then be thoroughly checked by voltage measurement, by the resistance measurement, or by simple replacement of parts until the defective one is found.

When making stage gain measurements in receivers, the value of the applied signals must be low enough to prevent the AVC system from functioning; otherwise, the measurements will not be accurate. In the Service Instruction Manual, the recommended signal values are usually stated in terms of the reference value to be used at the output meter.

Test Probe Substitution

Using a test equipment probe with equipment other than that for which it was designed may result in considerable error. Any differences in the internal resistance of the probe and input circuitry of the equipment precludes substitution without calibration. For example, the internal resistance of a 10:1 probe is, in most cases, nine times higher than the input circuitry of the equipment. It should be noted that 2:1, 50:1, and 100:1 probes are available as well as 10:1 probes.

Test probes which are not recommended for specific equipments should not be used, because they may not have sufficient capacitive adjustment to preserve the waveshape of the observed signal. A sound rule is to use all test probes only with the equipment for which they were designed.

Voltage Checks

Voltage measurements are made at various points in the stage suspected of being at fault, and the observed voltage values are compared with the normal voltage values given in the Service Instruction Manual.

When making voltage checks for comparison with a chart, be sure to use a voltmeter with the proper ohms-per-volt rating (sensitivity). Voltmeters are connected in shunt with the circuit elements under test, resulting in circuit loading. (Circuit loading is discussed in Basic Electronics and in chapter 10 of this manual.) If the sensitivity of the test instrument is the same as that of the instrument used in making the readings on the chart, the loading effect will be the same in both cases, and the readings obtained are reliable. Another important point to remember is that if the meter sensitivity is too low, loading effect may be so severe as to prevent proper

13542

13543

operation of an otherwise normally functioning circuit.

From this comparison, the defect can often be isolated. Voltage checks are most effective when applied within a single stage, after previous checks have been made to localize the defect. This is true because modern electronic equipment is complex, and a great deal of time is required to check all the voltages present in all the stages.

Some electronic sets have built-in meters or plugs for front panel application of meters. These meters usually work in conjunction with a selector switch, and will read values of voltage or current at designated points. A defective stage can often be isolated in this manner.

Once the defective stage is isolated, it becomes a matter of point-to-point checking to isolate the fault within the stage itself. A voltmeter will pinpoint the trouble, but it often becomes necessary to use an ohmmeter to determine the exact cause of trouble, such as shorted capacitors, open resistors or transformers, or wire grounded to chassis.

Resistance Checks

Resistance checks are similar to voltage checks except that the power is removed from the set. Resistance values are measured with an ohmmeter, and the readings are compared with the normal values given in the maintenance publications. Resistance checking, like voltage measurement, is most effective after the trouble has been isolated to a particular stage. Reliance on resistance measurement alone is too time consuming to be efficient. After the trouble has been isolated, the ohmmeter is a very useful instrument and often quickly leads the technician to the cause of the trouble.

NOTE: In order to prevent damage to the ohmmeter, always be sure that there are no voltages present in the equipment prior to beginning the resistance checks. Turn off the power switches, discharge power supply and other large capacitors, and bleed off any other residual charges in the set. Also observe proper precautions when connecting or disconnecting the ohmmeter across large inductors.

A typical example of a routine resistance check applied to a single part is the ohmmeter method of checking electrolytic capacitors. A resistance measurement is made on the discharged capacitor, using the high resistance range of the ohmmeter. When the ohmmeter leads are first applied across the capacitor, the meter pointer rises quickly and then drops back to indicate a high resistance. The test leads are then reversed and reapplied. The meter pointer should rise again–even higher than before–and again drop to a high value of resistance. The deflections of the meter are caused when the capacitor is charged by the battery of the ohmmeter. When the leads are reversed, the voltage in the capacitor adds to the applied voltage, resulting in a greater deflection than at first.

Do not leave the ohmmeter connected across an electrolytic capacitor for any appreciable period of time. Electrolytic capacitors are polarity-sensitive, and reverse polarity of voltage (even from an ohmmeter) may cause excessive current which could result in overheating and possible explosion of the capacitor.

If the capacitor is open-circuited, no deflection will be noted. If the capacitor is short-circuited, the ohmmeter indicates zero ohms. The resistance values registered in the normal electrolytic capacitor result from the fact that there is some current leakage between the electrodes. Because the electrolytic capacitor is a polarized device, the resistance is greater in one direction than the other.

Should a capacitor indicate a short circuit, one end of it must be disconnected from the circuit and another resistance reading taken to determine if the capacitor is actually at fault.

Unless the ohmmeter has a very high resistance scale the deflection of the meter when checking small capacitors will not be noticeable. Even a scale of R x 10,000 is not sufficient for very small capacitors; the smaller the capacity the less leakage across the plates, therefore the more resistance.

When making resistance checks, be sure to determine what circuits are connected to the points where the checks are made. The Service Instruction Manual will indicate what resistance should be found at various checkpoints throughout the set, and will contain a complete schematic of the set as well as a circuit schematic of the stage under test. The schematics may set up conditions under which voltage and resistance measurements are to be made, such as positions of switches and control knobs, relays energized

13543

or deenergized, tube in socket, etc. These conditions will duplicate the conditions under which the measurements were first made. A typical condition might be: "Power switch OFF–all controls on the control box fully CCW (counterclockwise)." It is important that these instructions be followed to obtain accurate values to compare with specified values. Otherwise incorrect values may be obtained.

Defective Components

Before replacing a defective part it is necessary to determine if such an operation may be performed by the unit or squadron. This is determined by the level of maintenance that has been assigned to the squadron. Increasing complexity and compactness of electronic equipment have resulted in a trend toward replacement of subassemblies rather than individual parts. This trend is caused by the necessity of exact parts replacement, and the difficulty of working in small spaces where even the amount of solder used on a connection can be of importance. However, there are many parts that may be replaced at any level of maintenance. The general rule is to replace any defective part with an exact duplicate.

Publications may be consulted to aid in obtaining information (such as stock number and description) about a particular part. The publications which will most often be used when ordering parts are the IPB and the Section R list for the particular equipment under repair. Chapter 4 of this training manual explains the use of the IPB and the Section R lists, and also the Standard Aeronautical Electronics Material Section R, NavWeps 00-35QR-4.

Should it become necessary to replace a part with a substitute, the technician must make sure that the substitute part is a proper replacement. With resistors, for instance, several characteristics must be considered–ohmic value, wattage rating, tolerance, physical size, and type of construction. Capacitors involve consideration of physical size, capacity, tolerance, temperature coefficient, and voltage rating. Plugs and connectors will almost invariably have to be exactly as prescribed since it is difficult to find items of this type that are interchangeable. Familiarity with the IPB is a definite asset to the technician who must determine exactly what part to order.

Basic Electronics contains information on color codes for capacitors and resistors. Refer to this manual for information on standard codes, specifications, physical shapes, methods of reading, and tolerances.

Checking After Repair

No repair job is complete until the repaired unit or set is reinstalled and actually operating properly. The set must be bench checked after the trouble is remedied, usually before the set is completely reassembled, and any alinement adjustments necessary to assure proper operation should be made. After reassembly of the set–replacement of dust and shielding covers, installation of set in outer case (and pressurization if necessary)–a final bench operational check should be performed. Oftentimes a shield or plate that has been installed will touch a bare wire or other contact and will render the set inoperative, or cause substandard operation. It is much better to discover such a fault at the bench than in the aircraft.

After the set is reinstalled in the aircraft and properly secured for flight, it must be given a final operational test. It cannot be assumed that because the set operated properly on the bench it will do so in the aircraft. The most important test is an operational check under exact operating conditions. When the set performs properly in the aircraft and is securely mounted, the discrepancy sheet may be signed. This signature indicates that the electronic set should operate properly under normal flight conditions.

The troubleshooting information described in the preceding paragraphs is summarized in figure 13-2, which shows in chart form a general troubleshooting procedure. The directions given in blocks 1 through 5 are steps to be used in locating trouble, and the directions given in blocks 6 and 7 are steps in repairing the set. (Steps 2, 3, 4, and/or 5 may sometimes be eliminated, but steps 6 and 7 will always be followed.)

13544

REPAIR INFORMATION

As was mentioned previously, increasing complexity and compactness of electronic equipment have caused a trend toward replacement of subassemblies rather than individual parts. This trend is caused by the necessity of exact parts replacement, and the difficulty of working in small spaces where even the amount of solder used on a connection can be of importance. However, there are many parts that will need to be replaced, and the rule is to replace a defective part with an exact duplicate.

The trend toward replaceable units has led to several new methods of construction of electronic equipment. Two examples are MICRO-ELECTRONICS and PRINTED CIRCUITS. These circuits are designed for speed and economy of manufacture, and speed and ease of maintenance, as well as saving of space and weight.

SOLDERING

Soldering operations are a vital part of electronics maintenance procedures. It is a manual skill which can and must be learned by all personnel assigned electronics maintenance shop duties. Practice is required to develop proficiency in the techniques of soldering; however, practice serves no useful purpose unless it is founded on a thorough understanding of basic principles. This discussion is devoted to providing information regarding some important aspects of soldering operations.

AT.261

Figure 13-2.–Troubleshooting procedure.

Soldering Iron

Proper preparation of the soldering iron is essential. The iron to be used should be selected on the basis of heat required. A 100-watt iron is satisfactory for splices and terminals; a 30-watt iron should be used for repair of printed circuits.

The tip must be free of oxide, scale, and carbonized flux, and should be smooth and completely tinned prior to use. Solder dissolves copper gradually, causing pits in the tip. Such pits should be filed smooth and the tip retinned.

During use, periodically wipe the tip to remove excess solder and flux.

Temperature

Both the solder and the material to be soldered must be heated to a temperature which allows the solder to flow. If either is heated inadequately, "cold" solder joints result. Such joints do not provide either the physical strength or the electrical conductivity required. Appreciably exceeding the flow point temperature, however, is likely to cause damage to the parts being soldered. Various types of solder flow at different temperatures. In soldering operations it is necessary to select a solder that will flow at a temperature low enough to avoid damage to the part being soldered, or to any other part or material in the immediate vicinity.

The duration of high heat conditions is almost as important as the temperature. Insulation and many other materials in electronic equipment are susceptible to damage from heat. They are damaged if exposed to excessively high temperatures, or deteriorate if exposed to less drastically elevated temperatures for prolonged periods. The time and temperature limitations depend on many factors–the kind and amount of metal involved, the degree of cleanliness, the ability of the material to withstand heat, and transfer and dissipation characteristics of the surroundings.

Soldering Process

Cleanliness is a prime prerequisite for efficient, effective soldering. Solder will not adhere to dirty, greasy, or oxidized surfaces. Heated metals tend to oxidize rapidly, and the oxide must be removed prior to soldering. Oxides, scale, and dirt can be removed by mechanical means (such as scraping or cutting with an abrasive) or by chemical means. Grease or oil films can be removed by a suitable solvent. Cleaning should be accomplished immediately prior to the actual soldering operation.

Items to be soldered should normally be tinned before making mechanical connection. When the surface has been properly cleaned, a thin, even coating of flux may be placed over the surface to be tinned to prevent oxidation while the part is being heated to soldering temperature. Rosin core solder is usually preferred in avionic work, but a separate flux may be used instead. Separate flux is frequently used when tinning wires in cable fabrication. Acid core solder or acid flux should be avoided due to its corrosive action.

The tinning on a wire should extend only far enough to take advantage of the depth of the terminal or receptacle. Tinning or solder on wires subject to flexing causes stiffness, and may result in breakage.

The tinned surfaces to be joined should be shaped and fitted, then mechanically joined to make good mechanical and electrical contact. They must be held still with no relative movement of the parts. Any motion between parts will likely result in a poor solder connection.

SOLDERED CONNECTIONS.–Frequent arguments occur in electronics maintenance shops concerning the proper method of making soldered connections to terminals and binding posts. For many years it was considered necessary to wrap the lead tightly around the terminal, so as to provide maximum mechanical support and strength. According to MIL-S-6872, General Specification for Soldering Process, "The parts to be joined shall be held together in such a manner that the parts shall not move in relation to one another during the soldering process. The joint shall not be disturbed until the solder has completely solidified."

The Navy Electronics Laboratory tested many standard capacitors and resistors soldered to terminals of various types. The joints were then subjected to vibrations far in excess of those encountered in military ships, aircraft, and armored vehicles. The connections were made with various degrees of wrapping around the terminals, with main reliance for physical strength being placed on the solder. As a result of this test and other conducted by other organizations, the joints illustrated in figure 13-3 are recommended. Wrappings of three-eights to three-fourths turn are usually recommended so that the joint need not be held during the application and cooling of the solder.

Excessive wrapping of leads results in increased heat requirements, more strain on parts, greater difficulty of inspection, greater difficulty of assembly and disassembly of the joints, and increased danger of breaking the parts or terminals during desoldering operations. Insufficient wrapping may result in poor solder joints due to movement of the lead during the soldering operation.

The areas to be joined must be heated to or slightly above the flow temperature of the solder. The application of heat must be carefully controlled to prevent damage to components of the assembly, insulation, or nearby materials. Solder is then applied to the heated area. Only enough solder should be used to make a satisfactory joint. Heavy fillets or beads must be avoided.

Solder should not be melted with the soldering tip and allowed to flow onto the joint. The joint should be heated and the solder applied to the joint. When the joint is adequately heated, the solder will flow evenly. Excessive temperature tends to carbonize flux, thus hindering the soldering operation.

No liquid should be used to cool a solder joint. By using the proper tools and soldering technique, a joint should not become so hot that rapid cooling is needed.

If, for any reason, a satisfactory joint is not initially obtained, the joint must be taken apart, the surfaces cleaned, excess solder removed, and the entire soldering operation (except tinning) repeated.

After the joint has cooled, all flux residues should be removed. Any flux residue remaining on the surface of electrical contacts may collect dirt and promote arcing at a later time. This

13546

cleaning is necessary even when rosin-core solder is used.

Connections should never be soldered or desoldered while equipment power is on or while the circuit is under test. Always discharge any capacitors in the circuit prior to any soldering operation.

MICROMAINTENANCE

Microelectronic technology by itself will not solve the maintenance problem. In spite of the greatly increased reliability, failures will still occur. When they do, the faulty items must be isolated and repaired or replaced.

With the discrete miniature component (transistor, resistor, capacitor, etc.), the maintenance technician can test individual circuit elements and thus determine the cause of failure. Repairs can then be made by replacing the faulty component.

With the integrated circuit, replacement of an individual part is impossible because the unit is designed and exists only as a complete functional element. The maintenance process then becomes a matter of isolation and replacement of the defective "chip," "flat-pack," board, or module.

Modules

Modular assemblies are mechanically more rugged than conventional circuits. They are, however, susceptible to damage from improper handling, electrical overload, or overheating. Techniques of maintenance and servicing are similar to those used with conventional circuits, but require somewhat more care in execution.

The small size and close spacing of the parts within the assembly require more care and smaller tools than are normally required in conventional maintenance. Additional devices and maintenance aids are of great help in developing the precision needed for such close work. Many components are inherently susceptible to damage from various causes. These factors require modification of some of the basic maintenance techniques and the use of some new ones.

Figure 13-3.–Wrapping of terminals for soldering.

13547

13246

2. Dashed or invisible lines. - These lines (short dashes about $\frac{1}{8}$ inch long) indicate edges, surfaces, and shapes of parts that are invisible, that is, hidden by another part of the object.

3. Center lines. - These lines are drawn as a series of thin long and short lines. They are quite important for centering or locating parts. The center line often serves as a line from which measurements are taken.

4. Dimension and extension lines. - Dimension lines indicate the extent of a given dimension. They terminate in an arrowhead which touches the extension line. Both extension and dimension lines are usually drawn with a harder pencil. This is done to enable one to see the line thickness differentiation between object and dimension and extension lines.

FIG. 2

5. Section or cross hatch lines. - These lines "shade" that portion of an object which has been "cut" by a cutting plane (Fig. 2). Sometimes section lines are drawn in a certain pattern to indicate a particular kind of material. If this be the case, the employer will notify the draftsman and supply him with a chart showing different symbols for different materials. Section lines are usually drawn to the convenient angle of 45°, using a triangle to obtain this result. The section line itself should be similar in weight to a dimension or extension line.

Component damage during maintenance is usually the result of excess heat during repair, reversed polarity of ohmmeters while checking for continuity, application of excessive voltages or signal magnitudes during testing, rough handling, or use of the wrong tools or materials.

Loosening connections, disconnecting parts, inserting or removing transistors, and changing modular units should not be done with the power on or while the circuit is under test. These actions (or a loose connection of any type) will cause an inductive kickback, which may damage the component.

It is also important to remove any capacitive charge from parts, tools, or test equipment before connecting them to any modular unit. A grounding clip should be connected from the item to the modular chassis before making any other contact. When disconnecting, the grounding clip should be removed last.

Leads to transistors, printed circuit boards, etc., as well as many miniature components are easily damaged in handling, stowage, or shipping. Proper precautions should be used at all times.

It should be emphasized that these miniature components and circuits can be repaired, if adequate care and proper techniques are used.

Maintenance Aids

In maintenance of microcircuits special devices are needed to extend the vision, aid the reach, and act as a third hand for the technician. Special tool and device requirements depend on the equipment to be serviced and on the maintenance operations involved. Many of the tools and devices discussed in this section are useful in all maintenance activities; others have limited applicability. The assortment of tools should be kept to the minimum required for effective and efficient maintenance of assigned equipment. A few useful special tools are shown in figure 13-4.

Many dental implements no longer usable for their original purpose can be readily adapted for use by the technician. These include various knives for scraping protective coatings and excess solder, brushes for cleaning, probes and mirrors for inspecting in crowded spaces, and drills for making small repairs. Tweezers and surgical hemostats are useful for grasping and holding small parts. Although they may also be used as heat shunts in soldering, their effectiveness is limited. A more desirable heat shunt is described later in this section. Hypodermic syringes (not shown) are useful in oiling hard-to-reach points.

A pin vise is useful in drilling through plastic, bakelite, or the copper-ribbon conductor strips of a printed circuit board. It may also be used to clean solder from hollow receptacles and terminals. In addition, it can hold many sizes and shapes of hooks and probes made from spring wire. These attachments are useful in inspection and servicing in confined spaces.

A magnifying device for inspecting minute parts is essential. If the magnifier is mounted on a stand it leaves the technician with both hands free for other tasks.

When working on a printed circuit or terminal board which has been removed from its mounting, the work must be held firmly. An easily built device suitable for this purpose is the jig shown in figure 13-5. The jig will provide support and prevent flexing or slipping. Securing the jig to the worktable leaves the technician with both hands free during the maintenance process.

For any desoldering operation, the part should be mounted so that the terminals are pointed out and downward. Place the soldering iron under the terminals so the solder flows away from the joint. To resolder the joint, invert the part.

A drawer or box with a white cloth can be used to catch any small parts dropped during maintenance. A drawer and sheet (or a cigar box and handkerchief) should prove adequate. (See fig. 13-6) in attaching the cloth, leave a little slack to form a pocket in the middle. When the jig (fig. 13-5) is mounted immediately above the trap any part dropped should find its way to the center of the cloth.

PRINTED CIRCUITS

Although maintenance procedures for printed circuits are similar to those for other circuits, they require more skill and care. Any defective part should be pinpointed by careful analysis of the symptoms before attempting to trace trouble on a printed circuit board.

13548

SOLDERING AIDS

AT.263

Figure 13-4.–Special tools.

Breaks in the conducting foil strip can cause either permanent or intermittent trouble. When searching for a break in the foil, first determine whether the strips have a protective coating. If so, it will be necessary to penetrate this film when checking for continuity. A needlepoint probe works very nicely.

Use a multimeter or an ohmmeter for checking continuity. Use a meter that passes no more than one milliampere. If the circuit contains transistors or other semiconductors, observe proper biasing conditions.

First check for continuity from one end to the other of each strip (being sure to penetrate the protective coating, but being careful not to damage the strip). If an open is indicated, move the probes one at a time until continuity is indicated. The break then lies between the last two positions of that probe. Carefully inspect the break to determine its extent and the repair process needed.

If the break is small, carefully scrape away any protective coating, clean the area with a firm bristle brush and an approved solvent, and flow solder over the break as indicated in figure 13-7 (A). If there is any indication that the strip might peel loose from the board, bridge the break with a small section of bare wire as indicated in figure 13-7 (B). Apply solder along the entire length of the wire to bond it firmly to the

13549

13548

Figure 13-5.–Jig for holding terminal blocks.

13550

AT.265

Figure 13-6.–Trap for catching dropped parts.

conducting strip. Keep the solder within the limits of the strip being repaired, to prevent the solder from flowing onto or near an adjacent strip. Be careful not to overheat any part of the area.

If a strip is burned out or fused, cut and remove the damaged strip and replace it with a wire soldered from terminal to terminal on the board.

A printed circuit board can withstand only a limited amount of flexing. Excessive flexing results in a broken board, which must then be replaced. When working on a board which is still mounted in its normal location, never use pressure. When the board is removed from its mounting, use the jig described earlier, and never use pressure.

After repairs are completed, thoroughly clean the board, restore the protective coating, and allow to dry thoroughly before reinstalling or applying power to the circuit.

Removal of transistors, tube sockets, or other parts from a printed circuit board often requires the simultaneous movement of several soldered connections. For this purpose use the pencil type soldering iron and special tips when possible. Remove excess solder from each connection, using a scribe or needle probe to scrape away the solder. Do not rock or pry the part to loosen the connection–rocking may damage the board. When all connections are free, simply lift the part.

To install the replacement part, solder each connection separately, in turn.

AT.266

Figure 13-7.–Repairing breaks in foil.

SEMICONDUCTORS

Transistors, unlike vacuum tubes, are very rugged in that they can tolerate vibration and a rather large degree of shock. Under normal operating conditions they will give dependable service over a long period of time. However, transistors are subject to failure when subjected to even minor overloads. Crystal detectors are also subject to failure or deterioration when subjected to electrical overloads; in addition they will deteriorate from long periods of normal use.

In order to determine the condition of semiconductors, various test methods can be used. In many cases it is possible to substitute a transistor known to be good for a questionable one; and thus determine the condition of a suspected transistor. This method of test is highly accurate and sometimes expeditious. However, indiscriminate substitution of semiconductors in critical circuits is to be avoided. When transistors are soldered into equipment, substitution becomes impracticable; it is generally desirable to test these transistors in their circuits.

13551

Since certain fundamental characteristics are an indication of the condition of semiconductors, test equipment is available for determining these characteristics with the semiconductor both in and out of their circuits. Crystal-rectifier testers normally test only the forward and reverse current ratio of the crystal. Transistor testers are capable of measuring several characteristics, such as the leakage current (I_{CO}), the current gain (beta), and the four-terminal network parameters. The most useful characteristic for test purposes is determined by the type of circuit in which the transistor will be used. The beta measurement is preferred for a-c amplifiers or oscillator applications. For switching-circuit applications, a direct-current measurement may be more useful.

Semiconductor Designation

Semiconductors are designated by the use of number and letter combinations that have been accepted as standard. The first number indicates the number of junctions and the letter "N" indicates a semiconductor. The number following the letter indicates the registration order. An example is the 1N21B. The "1" preceeding the "N" indicates a diode. The "N" indicates a semiconductor. The 21B indicates the 21st registration and the "B" indicates a modification of a 1N21A semiconductor.

Transistors also are identified by the number-letter-number sequence, that is, a 2N130 would be a triode transistor, registration number 130. Even though the above information is considered to be standard, different manufactures will sometimes use their own numbering system.

Semiconductor Basing and Basing Diagrams

Diodes have only two leads and a dot or color indicates the cathode terminal. Transistor leads generally have a color dot to indicate the collector lead or the collector is spaced farther from the other leads. The lead farthest from the collector, in line, is usually the emitter and the base lead is between the collector and emitter leads. This is shown in figure 13-8 (A). When the leads are evenly spaced, a red dot indicates the collector, as shown in figure 13-8 (B). If the base is circular, a red line indicates the collector and the emitter lead is the shortest lead. This is shown in figure 13-8 (C). In figure 13-8 (D), the triangular arrangement is off-set and the lead opposite the blank quadrant is the base lead. The collector is the first lead clockwise from the base. In power transistors, the collector lead is usually connected to the mounting base and the emitter lead will be identified by a color, as shown in figure 13-8 (E). One method of identifying leads of tetrode type transistors is shown in figure 13-8 (F).

Whenever a doubt exists regarding a particular type of semiconductor, a transistor manual or manufacturer's specification sheet should always be consulted.

SEMICONDUCTOR MEASUREMENTS

Because of the reliability of semiconductor devices, servicing techniques developed for transistorized equipment differ from those normally used for vacuum tube circuits. Vacuum tubes are usually considered to be the circuit component most susceptible to failure, and are therefore, normally the first components to be tested. Transistors are capable of operating in excess of 30,000 hours at maximum rating without appreciable degradation, and are often soldered into the equipment in the same manner as resistors and capacitors.

Substitution Test

Substitution of a crystal diode or transistor, known to be in good condition is a simple method of determining the quality of a questionable semiconductor device. This technique should be used only after voltage and resistance measurements are made to insure that there is no circuit defect that might damage the substituted semiconductor device. If more than one defective semiconductor is present in the equipment section where trouble has been localized, this method becomes cumbersome, since several semiconductors may have to be replaced before the trouble is corrected. To determine which stage failed and which semiconductors are not defective, all of the removed semiconductors must be tested. This can be accomplished by observing whether the equipment operates cor-

13523

17552

AT.267

Figure 13-8.–Transistor lead identification.

rectly as each of the removed semiconductor devices is reinserted into the equipment.

TRANSISTOR MEASUREMENTS

When trouble occurs in transistorized equipment, power supply voltage measurement, waveform checks, signal substitution or tracing methods are normally the first tests made. If a faulty stage is isolated by one of these test methods, voltage, resistance, and current measurements can be made to locate the defective part. When making these measurements care must be taken to make certain that the voltmeter resistance is high enough to have no appreciable effect upon the voltage being measured, and that the current from the ohmmeter will not damage the transistor. If the transistors are not soldered into the equipment, it is usually advisable to remove the transistors from their sockets during resistance tests. Transistors should be removed from or reinserted into their sockets only after power has been removed from the stage, since damage by surge current may otherwise result.

Transistor circuits other than pulse and power amplifier stages are usually biased so that the emitter current is in the vicinity of 0.5 to 3 milliamperes and the collector voltage is 3 to 15 volts. The emitter current can be measured by opening the emitter connector and inserting a milliammeter. When making this measurement, some change in bias should be expected due to the meter resistance. The collector current can often be determined by measuring the voltage drop across a resistor in the collector circuit and calculating the current by ohms law. If the transistor itself is suspected, it can be tested by the method described previously.

Resistance Test

An ohmmeter can be used to test transistors by measuring the emitter-collector, base-

13553

emitter, and base-collector forward and back resistances. Check the ohmmeter handbook to determine the polarity of the test leads. Some models apply reverse voltage from the internal battery.

CAUTION: Any ohmmeter used which is capable of delivering current in excess of 1 millampere may damage the transistor. USE ONLY AN APPROVED TYPE OHMMETER.

A back-to-forward resistance ratio on the order of 500 to 1 should be obtained for the collector-to-base and emitter-to-base measurements. The forward and back resistances between the emitter and collector should be nearly equal. All three measurements should be made for each transistor tested, since experience has shown that transistors can develop shorts between the collector and emitter and still have good forward and back resistance for the other two measurements.

Because of shunting resistances in transistor circuits, it will normally be necessary to disconnect at least two transistor leads from the associated circuit for this test. Caution must be exercised during this test to make certain that current during the forward resistance tests does not exceed the rating of the transistor.

HANDLING TRANSISTORS

Transistors, although generally more rugged mechanically than vacuum tubes, are susceptible to damage by excessive heat and electrical overload. The following precautions should be taken in servicing transistorized equipment:

1. Test equipment and soldering irons must be checked to insure that there is no leakage current from the power source. If leakage current is detected isolation transformers must be used.

2. Ohmmeter ranges which require a current of more than 1 milliampere in the test circuit should not be used for testing transistors.

3. Battery eliminators should not be used to furnish power for transistor equipment because they have poor voltage regulation and, possible, high ripple voltage.

4. The heat applied to a transistor, when soldered connections are required, should be kept to a minimum by using a low-wattage soldering iron and heat shunts, such as long-nose pliers, on the transistor leads between the iron and the transistor.

5. All circuits should be checked for defects before a transistor is replaced.

6. The power should be removed from the equipment before replacing a transistor or other circuit part.

7. When working on equipment with closely spaced parts, conventional test probes are often the cause of accidental short circuits between adjacent terminals. Momentary short circuits, which rarely damage a vacuum tube, may ruin a transistor. To avoid accidental shorts the test probes can be covered with insulation for all but a very short length of the tips.

SERVICING SEMICONDUCTOR CIRCUITS

Most new circuit design is based on the use of semiconductors. While some devices operate safely at high temperatures, the majority of transistors and crystal diodes in present use are particularly sensitive to temperature.

When transistors are mounted in sockets, they should be removed from the sockets before beginning any soldering operations on the terminals. Some transistors and most crystal diodes in printed circuits, however, are soldered directly in place. All connections must be desoldered before the semiconductor can be removed. Semiconductors cannot safely withstand the heat produced even with the pencil soldering iron. It is necessary, therefore, to use a heat shunt.

The soldering gun should not be used to solder or desolder semiconductor components in equipment. The strong electromagnetic field produced by the gun may cause induced currents great enough to damage the component.

Even conventional irons should be grounded to the chassis of transistorized equipment under repair, as mentioned previously, to prevent damage from accumulated electrical charges.

Semiconductors and many other miniature components are extremely susceptible to damage from electrical overloads. The maximum ratings for components are usually given in the technical manuals and in the charts and tables supplied for each equipment or major component. These ratings should not be exceeded.

13554

13222

Transistors and similar components require various power supply connections. When preparing a unit for operation on the test bench or in a breadboard type hookup, check the voltages and their polarities against the tables and drawings before activating the power. When using an ohmmeter for continuity testing, check the range and short circuit current rating of the meter before attaching it to the transistor.

Reversing the plate voltage on a triode vacuum tube will generally keep the tube from operating, but will normally not damage the tube. Semiconductors, however, are polarity-sensitive. Reversing the collector voltage polarity of a transistor or other semiconductor may ruin it instantly and permanently.

Leakage current from test equipment to the modular unit can also destroy transistors and other semiconductors. To prevent this, the use of an insolation transformer is recommended for those test sets which do not operate with transformer supplies to produce their operating voltages. In any event, the use of a grounding strap is recommended for all test equipments and instruments used in servicing or testing these circuits. The ground should be connected first to the module chassis, then to the test equipment ground post or chassis.

High magnitude pulses will also destroy transistors. Test equipment should be connected with minimum output or maximum attenuation settings, and gradually adjusted to the desired level.

TERMINAL BOARDS

It is often possible to replace a defective resistor or capacitor without removing the board from the chassis. If the leads extending from the defective component are long enough for a replacement part to be soldered to them, they may be cut where they enter the defective component. If the leads are not long enough, it is possible to get extra length by the method shown in figure 13-9. Cut the part in half and crush each half to take advantage of the lead length within the part. Make a hook in the remaining length of lead, then connect the new part.

When any soldering operation is necessary, use the pencil iron and its special tips, or the improvised tips described previously, with a ground lead connected from the tip of the soldering iron to the chassis of the part. Usually it is more convenient, and it is always safer, to completely remove the module and work on an insulated surface, using a jig.

AT.268

Figure 13-9.–Replacing resistor.

Any part to be removed should never be pried or forced loose. Any attempt to force a part loose may result in a broken or separated printed circuit panel. If the terminals do not pass easily through their holes, chances are that all the solder has not been removed. If any solder is left in the terminal hole after removing the leads, apply the soldering iron to the hole just long enough to soften the solder, and then gently poke the softened solder out with a toothpick, scribe, or small brush; or if necessary use a pin vise and drill.

RESISTORS

When a resistor must be replaced, one of the important considerations in selecting the replacement is the wattage value. In general, the wattage rating is a measure of the ability of the resistor to dissipate heat, and the value is related to the physical size of the resistor.

The selection of a safe wattage value is based on a consideration of the working conditions of the resistor in the circuit. Consider as an example the replacement of an 850-ohm resistor with one of equal ohmic value but which has a tolerance of ±20 percent. Suppose the normal voltage existing across the resistor is 40 volts. Because of the 20 percent tolerance, the actual resistance of the replacement may be as much as 1,020 ohms or as little as

13555

680 ohms. Taking the lesser value (the more unfavorable from a heat-dissipating standpoint), the power that may be developed in the resistor under circuit conditions is found as follows:

$$W = \frac{E^2}{R}$$

$$W = \frac{40 \times 40}{680}$$

W = 2.35 watts, approximately

A resistor should be capable of dissipating from 1.5 to 2 times the power actually encountered, to allow sufficient margin of safety. In the example, this value is not more than 4.7 watts. Since a 5-watt resistor is the next standard size above the 4.7-watt value, this is a desirable wattage rating for the replacement.

Under emergency conditions, it is sometimes necessary to combine resistors in series or in parallel to obtain a desired resistance value. When this is done, care should be taken to avoid a voltage distribution (or current distribution) which causes any low-wattage resistor in the combination to dissipate an excessive amount of heat. For example, suppose two 10-watt resistors of 1-ohm value were combined in series with a 2-watt resistor of 10 ohms. The total wattage dissipated when the series combination is connected across 12 volts is 12 watts. But the power dissipated by the 10-ohm, 2-watt resistor is 10 watts, a value far in excess of its capabilities. It is necessary to consider each resistor in the combination and select a wattage value based on the voltage developed across the individual unit.

AIRCRAFT AND EQUIPMENT WIRING

Wiring in aircraft normally runs from point to point, or plug to plug, without interruption (no splices). However, there are methods of splicing wires in aircraft that are acceptable as permanent splices.

Wiring in aircraft is identified by a system of numbers and letters stamped on each wire, as described in chapter 4 of this manual. The Service Instruction Manual and the Maintenance Instructions Manual give the number of each wire involved in cabling of electronic equipment. Should it become necessary to trace and repair a wire in the aircraft, refer to these manuals to determine the routing of the wire involved.

Wiring data for all electrical and electronic systems in each model aircraft are contained in the Wiring Data section of the applicable Maintenance Instructions Manual. The diagrams are prepared separately for each circuit and provide all data necessary to understand the construction of each circuit, to trace each circuit within the system, to make continuity and resistance checks, and to perform specific troubleshooting on inoperative or malfunctioning circuits. Schematic diagrams for circuits and related components are found in those volumes of the Maintenance Instructions Manuals specifically covering a system or systems.

An excellent source of information in connection with power distribution and aircraft wiring is Installation Practices for Aircraft Electric and Electronic Wiring, NavWeps 01-1A-505. This manual presents the recommended practices and techniques to be used for installing, repairing, and maintaining aircraft electric wiring. It includes information under the following headings: Wire and cable preparation; general-purpose connectors; RF connectors and cabling; solderless terminations and splicings; thermocouple wire soldering and installation; bonding and grounding; bus bar preparation; conduit fabrication; installation of bus bars, conduit, junction boxes, protective devices, and terminal strips; electrical wiring installation; lacing and tying; safety wiring; and emergency repairs. This information is summarized in the following paragraphs. Refer to the manual for additional details.

CONNECTORS

In the discussion which follows, the word "connector" is used in a general sense. It applies equally well to connectors designated by "AN" numbers and those designated by "MS" numbers (fig. 13-10 (A)). AN numbers were formerly used for all supply items cataloged jointly by the Army and Navy. Many items, especially those of older design, continue to carry the AN designator, even though

13556

the supply system is shifting over to MS (Military Specification) numbers.

AN specification numbers for connectors have been generally superseded by MS numbers. However, many instances will occur in which connectors are still referred to as "AN connectors."

Inspection

Connectors are inspected when the major units that they connect are inspected. During this inspection, the mating parts of the connectors are separated and the contacts examined for corrosion. If corrosion is present, the surfaces are cleaned with a brush or clean rag and a noncorrosive solvent. The coupling ring is inspected for battered threads, and should be replaced if the threads are not in good condition. When attaching or detaching the connector, care should be taken to avoid damaging the coupling or bending the coupling nut. (See fig. 13-10(B).)

If the connector does not contain a moistureproofing compound, the conductors should be inspected where they are soldered to the pin contacts. Short circuits are often caused by a frayed strand of one conductor touching the solder cup of another conductor within the plug. If this is the case, the frayed strand may be clipped. Check to see that all soldered connections are adequate and that no cold solder joints exist.

Connectors do not require lubrication except for the coupling ring threads. Occasionally, they should be given a light coat of antiseize compound to insure smooth operation.

Maintenance

At times, operating conditions demand that ordinary electrical connectors be given a moistureproofing treatment. The basis of moistureproofing is the application of a sealing compound.

Moistureproofing reduces failure of electrical connectors and reinforces the wires at the connectors against failure caused by vibration and lateral pressure, both of which fatigue the wire at the solder cup.

The sealing compound also protects electric connectors from corrosion and contamination by excluding metallic particles, moisture, and aircraft liquids. As a result of its improved

AT.269

Figure 13-10.–(A) Connector shells; (B) exploded view of a connector.

6. Cutting plane lines. - A cutting plane line indicates where one view has been "cut" in order that a sectional view may be drawn to show the shape of the object in the plane of the cut.

7. Break lines. - Break lines indicate that a portion of an object has been omitted from a drawing (Fig. 1).

1353

dielectric characteristics, it reduces the possibility of arc-over between pins at the back of electric connectors.

The sealant is provided in kit form through the normal supply channels. Sealing (or potting, as it is called) is not required on environment-proof E connectors or connectors located in areas where the temperature exceeds 200° F. The sealing compound deteriorates after long exposure to ambient temperature above 200° F.

The detailed instructions for performing sealing operations may be obtained from the current Electronic Material Change covering this subject. A summary of the procedures involved in sealing a connector is as follows:

1. Prepare a used connector by removing existing sealants and by cleaning. The cleaning solvent used must clean thoroughly, evaporate quickly, and leave no residue. Remove all sleeving from the wires. Resolder loose or poorly soldered connections and add a length of wire approximately 9 inches long to each unused pin. Remove any excess rosin from around the pins and the insert; a stiff bristle brush is helpful in doing this. Now, repeat the cleaning, and then separate the wires evenly.

2. Thoroughly mix the accelerator and base compound (fig. 13-11). The ratio of the amount of accelerator to the amount of base compound is critical; therefore, the entire quantity of accelerator furnished must be added to the base compound.

3. Place the plugs or receptacles on a table, arranging them so that gravity will draw the sealer to the bottom of the plug. Box receptacles or plugs without back shells must be fitted with a mold made of masking tape or cellophane tape or equivalent. (See (A) of fig. 13-12.) This will retain the sealant during the curing process. If the back shell is used, apply a slight amount of oil to the inner surfaces to prevent the compound from adhering to it.

4. The compound is applied by a spatula, putty knife, or paddle. It should be packed around the base of the pins. The part being potted should be completely filled or at least to a point to cover three-eights inch of insulated wire. The compound is now allowed to cure; temperature will affect the curing time. The normal curing time is approximately 24 hours.

AE.65

Figure 13-11.–Combining accelerator with base compound.

If it is desired that the entire connector assembly (plug and receptacle) be sealed against fluid entering or collecting between the two parts, it is necessary that a rubber O-ring be fitted over the barrel of the plug. This will provide a seal when the two parts are engaged securely. If properly installed, this seal will prevent moist air from entering due to variations in temperature, altitude, or barometric pressure on the ground. Rubber packing O-rings are available for this purpose through normal supply channels. Due to the aging of these rings in service, it is necessary to examine them each time the connector is disassembled. If deteriorated, they must be replaced.

The purpose of soldering a short length of wire to each spare pin is to provide for two

13558

AE.66

Figure 13-12.–(A) Making mold from masking tape; (B) finished potted plug.

eventualities: to allow for growth requiring additional circuits to be included in the connector, and to reduce the need of repairing a single wire which may have failed with the connectors by making a splice to one of the spare wires.

CONDUCTORS AND TERMINALS

Although modern technical literature has been emphasizing the use of printed circuits and microelectronic components in contemporary electronic equipment, conductors are still important as a signal- or current-carrying device. (For the purpose of this discussion the term conductor will refer to both wire and cable.) As a significant part of operating equipment, conductors deserve appropriate attention.

Wire

For wire replacement work, the Maintenance Instructions Manual for the particular aircraft or equipment should first be consulted since it normally lists the wire used. When this information cannot be obtained from the manual, the repairman must select the correct conductor needed for the job. The three major factors involved in this selection in descending order of importance, are size, insulation, and the characteristics required to satisfy specific environments in which the wire must function.

CONDUCTOR SIZE.–For d-c applications, the allowable voltage drop and current-carrying capacity govern the choice of size. At radio-frequencies, the skin effect and inductance may become a controlling factor, although generally (except in inductors or RF transformers) these parameters need not be considered. Wire size is therefore basically a function of the current or the allowable resistance, except when this results in a very small conductor size.

Small conductors are difficult to handle and are subject to breakage in soldering or due to vibration. Experience has shown that these difficulties may be avoided by using No. 22 or No. 24 AWG for general circuit wiring and at least No. 20 AWG for parallel connected tube filaments. Solid wire should be used only for short jumper connections not exceeding 3 inches in length, unless the parts being connected are solidly mounted and not subject to vibration. Clamps or "dress lugs" are recommended for long leads. In other words, the use of stranded copper wire whenever possible is strongly recommended, although under extreme conditions of vibration or where high flexibility is required, oxygen-free copper is sometimes specified. Copperclad steel is another possibility for applications requiring greater strength and rigidity.

INSULATION.–A wide variety of insulating material is available, which makes its specification particularly important. Since each insulation has its peculiar characteristics, no single type is therefore always suitable for general usage. The major insulation requirements include good dielectric strength, high

13559

13558

damaged in the process. This eliminates the necessity of taping or tying an insulating sleeve over the joint.

Cable Splicing

A cable splice, other than one made with the crimp-on splice or connector, is employed as an emergency measure only. Solder may or may not be used, as the condition warrants, but in any case the splice should give a good electrical and mechanical joint without solder. The splice should be taped to give insulation equivalent to the rest of the cable. A permanent repair must be made as soon as possible.

Consult section XII of Engineering Handbook Series for Aircraft Repair, Aircraft Structural Hardware (AN 01-1A-8), and/or Installation Practices for Aircraft Electrical and Electronic Wiring, NavWeps 01-1A-505, for detailed information dealing with attaching cable terminals, forming terminals for emergency use, and repairing damaged or broken cables.

Terminal Blocks and Junction Boxes

Terminal blocks are made from an insulating material which supports and insulates a series of terminals from each other as well as from ground. They provide a means of installing terminals within junction boxes and distribution panels.

Two methods of attaching cable terminals to terminal blocks are illustrated in figure 13-14. In (A) of the figure a standard nonlocking nut is used. In this method of installation, the use of a lockwasher is necessary. The preferred method is shown in (B) of the figure. An anchor nut, or self-locking nut, is used and the lockwasher is retained for additional security. The use of anchor nuts is especially desirable in areas of high vibration. In both installations, it is required that a flat washer be employed, as shown in the drawing.

Junction boxes are installed to accommodate electrical terminals or other equipment, such as relays and transformers. Individual junction boxes are named according to their function, location, or equipment with which they are associated. Junction boxes are usually provided with a drain hole (except boxes labeled "vapor-

AE.67

Figure 13-14.–Installation of cable terminals on terminal block.

tight") located at the lowest point so that water, oil, condensate, or other liquids will not be trapped.

Insulating Sleeving

Insulating sleeving (commonly called "spaghetti") is used in electronic maintenance operations in many aviation activities. Among the operations involving use of the sleeving are the fabrication of cable connectors, connection to relays and terminal strips, crimped or soldered terminal lugs or splices, tie points on terminal strips or terminal boards, etc.

Support Clamps

Clamps are used to provide support for open wiring, and to serve instead of (or in addition to) lacing on open wiring. They are usually supplied with a rubber cushion. When used with shielded conduit, the clamps are of the bonded type (fig. 13-15(A)); that is, provision is made

AE.69

Figure 13-15.–Cable clamps.

for electrical contact between the clamp and conduit. Unbonded clips are used for the support of open wiring.

Long runs of cable between panels are supported either by a strap type clamp, shown in (B) of figure 13-15, or by a clamp of the type shown in (C) of the same figure. The preferred method of supporting cables for all types of runs is with the type shown in (C). When the strap type clamps are used, precautions must be exercised to insure that they will hold the cables firmly away from lines, surface control cables, pulleys, and all movable parts of the aircraft; these clamps should be used only as an emergency measure.

When cables pass through lightening holes, the installation should conform to the examples shown in figure 13-16. The cable should be routed clear of the edges of the lightening hole, to avoid any possibility of chafing of the insulation.

Lacing and Tying

Wire groups and bundles are laced or tied to provide ease of installation, maintenance, and inspection. The purpose of lacing or tying is to keep all cables neatly secured in groups and thus avoid possible damage from chafing against equipment or interference with equipment operation.

AE.70

Figure 13-16.–Routing cables through lightening holes.

TYING is the securing together of a group or bundle of wires by means of individual pieces of cord tied around the group or bundle at regular intervals. LACING is the securing together of a group or bundle of wires inside enclosures by means of a continuous piece of cord forming loops at regular intervals around the group or bundle.

A wire group is two or more wires tied or laced together to give identity to an individual system. A wire bundle is two or more wires or groups tied or laced together to facilitate maintenance.

Cotton, nylon, or Fiberglas cord is used for tying or lacing. The cotton cord must be waxed to make it moisture and fungus resisting. Nylon and Fiberglas cords are in themselves moisture and fungus resisting and are not usually waxed. Pressure sensitive vinyl electrical tape is used only where the use of tape instead of cord is specifically permitted.

When lacing or tying (fig. 13-17 and 13-18), observe the following precautions:

1. Lace or tie bundles tight enough to prevent slipping, but not so tight that the cord cuts into or deforms the insulation.

NOTE: Coaxial cables have been damaged by the use of lacing materials or by methods of lacing or tying wire bundles which cause a concentrated force on the cable insulation. Elastic lacing materials, small diameter lacing cord, and excessive tightening deform the interconductor insulation and result in short circuits or impedance changes. Avionics Bulletin No. 8 of May 1963 directs the use of the flat nylon braided waxed lacing tape (FSN 4020-730-2622-L980) for lacing or tying any wire bundles which include coaxial cables.

2. Do not place ties on that part of a wire group or bundle that is located inside a conduit.

3. Lace wire groups or bundles only when they are inside enclosures, such as junction boxes. Use double cord on groups or bundles larger than 1 inch in diameter. Use single or double cord for groups or bundles 1 inch or less in diameter.

13562

AT.270

Figure 13-17.–Lacing wire groups or bundles.

AT.271

Figure 13-18.–Tying wire groups or bundles.

In some instances groups or bundles may be secured with tape. (See fig. 13-18(B).) The following method should be employed:

1. Wrap tape around wire group or bundle three times, with a two-thirds overlap for each turn.

2. Heat-seal the loose tape end with the side of a soldering iron heating element.

Do not use tape for securing wire groups or bundles which may require frequent maintenance.

An excellent source of additional information in connection with power distribution is NavWeps 01-1A-505, Installation Practices for Aircraft Electric and Electronic Wiring. This manual presents the recommended practices and techniques to be used for installing, repairing, and maintaining aircraft electric wiring. It includes information under the following headings: Wire and cable preparation; general-purpose connectors; RF connectors and cabling; solderless terminations and splicings; thermocouple wire solderings and installation; bonding and grounding; bus bar preparation; conduit fabrication; installation of bus bars, conduit, junction boxes, protective devices, and terminal strips; electrical wiring installation; lacing and tying; safety wiring; and emergency repairs.

13563

BONDING

A bond is any fixed union existing between two metallic objects that results in electrical conductivity between them. Such a union results from either physical contact between conductive surfaces of the objects or from the addition of a firm electrical connection between them. Aircraft electrical bonding is the process of obtaining the necessary electrical conductivity between the component metallic parts of the aircraft. An isolated conducting part of an object is one that is physically separated by intervening insulation from the aircraft structure and from other conductors which are bonded to the structure.

A bonding connector provides the necessary electrical conductivity between metallic parts in an aircraft not in sufficient electrical contact. Examples of bonding connectors are bonding jumpers and bonding clamps. (See fig. 13-19.)

An aircraft can become highly charged with static electricity while in flight. If the aircraft is improperly bonded, all metal parts will not have the same amount of charge. A difference of potential will then exist between various metal surfaces. The neutralization of the charges flowing in paths of variable resistance, due to such causes as intermittent contact from vibration or the movement of the control surface, will produce electrical disturbances (noise) in the radio receiver. If the resistance between isolated metal surfaces is great enough, charges can accumulate until the potential difference becomes sufficiently high to cause a spark. In addition to creating radio interference, this also constitutes a fire hazard. In the case of lightning striking the aircraft, a good conducting path is necessary for the heavy current in order to minimize severe arcs and sparks which would damage the aircraft and possibly injure its occupants.

The aircraft structure is also the ground for the radio. For the radio to function properly, a proper balance must be maintained between the aircraft structure and antenna. This means the surface area of the ground must be constant. Control surfaces, for example, may at times become partially insulated from the remaining structure due to a film of lubricant on the hinges.

AT.272

Figure 13-19.–Bonding methods.

This would affect radio operation if the condition were not taken care of by bonding.

Bonding also provides the necessary low-resistance return path for single-wire electrical systems. This low-resistance return path also aids the effectiveness of the shielding, and provides a means of bringing the entire aircraft to the earth potential when it is grounded.

The reason for bonding may be summed up as follows:

1. To minimize radio and radar interferences by equalizing static charges that accumulate.

13564

2. To eliminate a fire hazard by preventing static charges from accumulating between two isolated members and creating a spark.

3. To minimize lightning damage to the aircraft and its occupants.

4. To provide the proper ground for proper functioning of the aircraft radio.

5. To provide a low-resistance return path for single-wire electrical systems.

6. To aid in the effectiveness of the shielding.

7. To provide a means of bringing the entire aircraft to the earth's potential and keeping it that way while it is grounded to the earth.

Bonding connection should be installed so that vibration, expansion or contraction, or relative movement incident to normal service use will not break the bonding connections or loosen them to such an extent that the resistance will vary during the movement. The bonding of most concern will be the bonding jumpers that are placed across shock mounts, used to support electronic equipment.

Since a primary objective for bonding is to provide an electrical path of low d-c resistance and low RF impedance, it is important that the jumper be a good conductor of ample size for the current-carrying capacity, have low resistance, and be as short as possible. Insofar as practical, parts should be bonded directly to the basic aircraft structure rather than through other bonded parts. Bonding jumpers should be installed in a manner so as not to interfere in any way with the operation of movable components of the aircraft.

Contact of dissimilar metals in the presence of an electrolyte, such as salt water, produces an electric action (battery action) which causes a pitting in one of the metals. The intensity of this electric action varies with the kinds of metals. Bonding frequently necessitates the direct contact of dissimilar metals. In such cases the metals used are of the kind that will produce a minimum of corrosion. The connections are also made so that if corrosion does occur, it will be in replaceable elements, such as jumpers, washers, or separators, rather than in the bonded or bonding members. Thus, washers made of the same material as the structural member should be used against the structural member, and washers of the same material as the bonded member should be in contact with that item.

Self-tapping screws should not be used for bonding purposes nor should jumpers be compression-fastened through plywood or other nonmetallic material. When performing a bonding operation, the contact surfaces should be cleaned of insulating finishes or surface films before assembly, and then the completed assembly refinished with a suitable protective finish.

Consult Installation Practices for Aircraft Electric and Electronic Wiring, NavWeps 01-1A-505, for more detailed information dealing with bonding.

SHOCK MOUNTS

Electronic equipment is sensitive to mechanical shock and vibration; therefore, units of electronic equipment are normally shock mounted to provide some protection against in-flight vibration and against launching and landing shock. The specific type shock mount is prescribed in the Maintenance Instructions Manual for the specific aircraft, and substitution should not be made.

Periodic inspection of shock mounts is required, and defective mounts should be replaced with the prescribed type. In the inspection, the main factors are chemical deterioration of the shock absorbing material, stiffness and resiliency of the material, and overall rigidity of the mount. If the mount is too stiff or too rigid, it may not provide adequate protection against the shock of launching and landing; if it is not stiff or rigid enough, it may permit prolonged vibration following an initial shock. When determining the limits of rigidity and resiliency, consideration must be given to the weight of the mounted unit as well as the amounts of positive and negative acceleration to which it is subjected.

Shock absorbing materials commonly used in shock mounts are usually electrical insulators. For the sake of safety, it is required that each electronic unit mounted in this manner must be electrically bonded to a structural member of the aircraft. (See fig. 13-19 (B).) The bonding strap should also be included in the inspection of the shock mounts, and defective or ineffective bonds should be replaced or reinstalled.

SAFETY WIRING

Before an installed unit can be considered secured for flight, it must be safety wired properly. Two common methods—the single twist and the double twist—are used. Figure 13-20 illustrates typical examples of each method.

Specific items which normally require safety wiring include cable connectors, drilled-head bolts or screws and nuts, thumbscrews and wingnuts on mounting racks, switchguards which are required to retain a switch in a specified position but which could be placed inadvertently into the wrong position, and most threaded items which do not use cotter pins or self-locking nuts.

The double twist method is the most common method of safety wiring, and should essentially be as shown in figure 13-20(A). The twisting may be accomplished by hand with the exception of the final few twists which should be done with pliers in order to apply tension and secure the ends of the wire properly. The safety wire should always be installed and twisted so that the loop around the head stays down and does not tend to come up over the bolthead, causing a slack loop. Extreme care must be used when twisting the wires together to insure that they are tight but not overstressed to the point where breakage will occur under slightly greater than normal load or vibration.

The single twist method of safety wiring may be used on small screws in a closely spaced area, if the screws form a closed geometrical pattern. Figure 13-20(B) illustrates a typical application where the single wire method may be used.

Finished ends of safety wire should be bent back or under to prevent injury to personnel (fig. 13-20(C)). The safety wire should be as short as practicable, and must be installed in such a manner that the pull on the wire is in the direction which tightens the movable item (fig. 13-20(D)).

When safety wiring widely spaced bolts by the double twist method, a group of three should be the maximum number in a series. When safety wiring closely spaced bolts, the number that can be safety wired by a 24-inch length of wire should be the maximum number in a series.

Torqued parts being safety wired should be torqued to recommended values and holes alined before attempting to proceed with the safetying operation. Never overtorque or loosen a torqued nut to aline safety wire holes.

Whenever a safety wire is broken for maintenance or other cause, it must be replaced using the proper procedure. Any time a required safety wire is not replaced, an in-flight failure may result.

QUESTIONS:

1. Which line is generally drawn heaviest on a drawing?
2. Which line centers or locates parts?
3. What does a line consisting of short dashes mean to you?
4. Which line terminates in an arrowhead?
5. Which line shades a portion of an object which has been cut?
6. At what angle is a section line drawn?
7. Which line indicates where one view has been cut?
8. Should dimension, extension, and section lines be drawn similar in weight?
9. Does a dimension line indicate the extent of a given dimension?
10. The center line often serves as a line from which measurements are taken. Explain.

ASSIGNMENT:

In the drawing below, identify the names of lines A through F.

1354

CHAPTER 14

ELECTRONIC MAINTENANCE, PART II

ENVIRONMENTAL PROBLEMS

Although the need for reliability in military avionics equipment has remained relatively constant since the start of World War II, the difficulty of attaining this reliability has increased. The continually increasing complexity of avionics equipment and the subjection of equipment to more and more rigorous environmental conditions are among the chief causes of equipment failure. For these reasons the technician should understand the effects of environmental conditions on the equipments and the design techniques used to minimize these effects.

The environmental factors that should be understood in order to maintain the design characteristics include temperature, humidity, pressure, and abrasive conditions.

TEMPERATURE

Extensive research has been conducted to develop external component parts that are better able to withstand operation under extreme temperatures. Extremely low temperatures cause brittleness in metal and loss of flexibility of rubber, insulation, and similar materials. Extremely high temperatures may cause deformity and deterioration of these items. Most internal component parts are not able to withstand these extreme temperatures.

Because equipment is normally installed in confined spaces aboard aircraft, the generated heat causes the temperature to rise; therefore, many units have fans installed to increase the air circulation, thus reducing the temperature within the unit. Most of the new models of aircraft utilize the electronic equipment compartment concept, and use blast air from outside the aircraft or from the aircraft's air-conditioning system for cooling.

HUMIDITY

Humidity, a measure of water content in the air, is a possible cause of avionic equipment or component failure. High humidity (that is, a high water content in the air) provides a possible environment for corrosion and fungus growth. A high moisture content in the air may cause short circuiting between points of high potential.

In certain cases the removal of heat from equipment requires the use of external air. If this external air has a high moisture content, the cooling may be accomplished by one of two ways. First, the high humidity air may be directed through an air jacket which surrounds the equipment. In this case the heat is removed without allowing the humid air to come in contact with the internal equipment components. Second, when the internal equipment components require direct air for heat removal, the direct air is passed through silica-gel crystals, removing the moisture from the air. It should be apparent that the second method is less troublesome because the first case does cause corrosion within the air jacket.

PRESSURIZATION

When high-voltage avionics equipment is operated at high altitudes without being pressurized, there may be the problem of arc-over. This is caused by the reduced dielectric strength of the air as it becomes less dense. To reduce the possibility of arc-over, the equipment is pressurized.

When troubles occur in the system, a check for evidence of arc-over should be made. This may be indicated by blown fuses, charred

13568

13568

insulation, and pitting of metal close to high voltages.

ABRASIVE CONDITIONS

Sand, dust, and other substances which are abrasive in nature affect many components. Generally these components are parts that are not sealed off from the atmospheric conditions. In some cases the abrasive material is formed even though the unit is sealed. Examples are generators, motors, and dynamotors which use brushes. Also the protective coating may be removed from a part by the movement of the abrasive material in the air that is used for cooling. This may allow the unprotected metal to corrode.

Modern aircraft configurations employ the use of air-conditioning systems for the purpose of cooling the avionics equipments. The external air is used to cool the heat exchanger while the internal air used to remove heat from the equipment may be pressurized. The use of the pressurized air for equipment heat removal minimizes the undesired environmental effects of temperature, humidity, arc-over, and abrasive conditions. An example of a single equipment air-conditioning system is shown in figure 16-18 of chapter 16. Multiple equipment packages utilize the air-conditioning system of the aircraft.

CORROSION CONTROL

In modern aircraft, the need for corrosion control has become a major concern in the availability and maintenance of our striking forces. This is because corrosion is something that destroys equipment and is active 24 hours a day. It is of the utmost importance that its nature be understood in order to combat corrosion.

Most of the useful metals used today have been refined from natural ores found in the earth's surface. These metals are extracted from the ore and are used in various combinations to form alloys with distinct properties. Some of these properties are light weight, strength, and resistance to extreme temperatures. These refined metals have a tendency to return to their natural state, but proper corrosion control will prevent this action taking place.

With the strength demands being made of metals, corrosion control becomes more important because corrosion weakens the metals, thereby causing structural failure. This type failure will cause aircraft safety to decrease and cost of repairs to increase.

CHEMICAL CORROSION

Most surface corrosion is chemical in nature and is generally caused by salts, acids, or gases coming in contact with the metallic surfaces of the aircraft or equipment.

Aircraft and their associated equipment which are based aboard ship are particularly vulnerable to salt spray and gases which originate on board a ship. Shore-based aircraft are also exposed to contamination, but to a somewhat lesser degree. Although salt spray and gases in the atmosphere cause rapid chemical corrosion, it should be understood that some corrosion will take place under the most ideal situations.

Chemical corrosion is a chemical process which is esentially the reverse of the process of extracting the metals from their ores. For the most part, metals occur naturally as metallic oxides. After refining, regardless of whether or not alloyed, base metals generally possess a tendency to return to their natural state. However, this is not sufficient in itself to initiate and promote this reversion. There must also exist a corrosive environment in which the significant element is oxygen. Corrosion, then, is the process of oxidation.

ELECTROCHEMICAL CORROSION

While chemical corrosion is generally readily apparent, electrochemical corrosion is insidious in its destruction. Electrochemical corrosion includes galvanic or dissimilar metals corrosion. This type of corrosion is caused by an exchange of electrons between two metallic areas of different activity (potential) by way of an electrolyte. Three conditions must be present in order for electrochemical corrosion to take place. The first condition is that two or more areas of metal are needed to act as electrodes. The second condition is the requirement of the presence of an electromotive force. The last requirement is the presence of an electrolyte to complete the formation of a cell.

13569

It is not necessary to know all the theories concerning electrochemical corrosion, but a brief understanding of the deterioration of metals will be beneficial in combating this type of corrosion.

An ordinary flashlight cell serves as a good subject to explain electrochemical corrosion. (See fig. 14-1.) The outside container is made of zinc and serves as the anode which is corroded as the cell is operated. The cathode of the chemical cell is the carbon electrode in the center of the cell. The moist ammonium and zinc chloride paste within the zinc container is the electrolyte which electrically connects the carbon electrode with the zinc anode.

If a conductor is connected externally to the electrodes of a cell, electrons will flow under the influence of a difference of potential across the electrodes from the zinc (-) through the external circuit to the carbon (+) returning within the electrolyte to the zinc. As the electrons flow, the zinc coating will oxidize. This oxidation is the same as corrosion. For a more detailed explanation of the operation of a cell, refer to Basic Electricity, NavPers 10086-B.

Since the only requirements for a cell are cathode, anode, and electrolyte, it should be apparent that the physical size of a cell is dependent only on the physical size of its components. A cell may be formed where a resistor lead is soldered to a terminal, two sheets of metal are joined, or around a rivet head and the adjacent metal. (See fig. 14-2 (A) and (B).) A cell may even be formed when an electrolyte is present on one piece of metal where two metallic crystals in the same alloy, but of different composition, are in electrical contact with each other. (See fig. 14-2 (C).)

Figure 14-1.–Dry cell, cross sectional view.

While the formation of one minute cell may be insignificant, it should be understood that a cell will continue to grow as long as the corrosion action is allowed to continue. This cell expansion may take place in a short period of time and become a significant structural safety factor due to the deterioration of the metal.

It should be apparent that the presence of an electrolyte allows corrosion to take place. The more efficient the electrolyte and the greater the potential difference between anode and cathode, the higher the corrosion rate (growth) will be. It should be noted that the anode and cathode are always present and cannot be removed; therefore, the solution to the problem of corrosion is to remove the electrolyte. When the electrolyte is removed, a cell no longer exists and corrosion is held to the minimum.

Both types of corrosion normally depend on moisture to form an electrolyte. Even moisture in the air is often sufficient to start the corrosion action. All attacks of corrosion start on the surface of the metal where it is exposed to the corrosive environment; and if allowed to progress, it will work its way into the core of the material. Since corrosion never originates in the core, there is always some form of evidence of corrosion on the surface.

CORROSION PREVENTION

Now that it is understood that the "villain" of corrosion is the electrolyte, the solution to corrosion prevention is to keep any electrolyte from coming into contact with the electrodes. This is accomplished by keeping a protective coating on the metallic surfaces.

Much has been done to improve the corrosion resistance of naval aircraft. This is in the area of improvement in materials, surface treatments, insulation, and protective finishes.

13570

AT.275

Figure 14-2.–Electrochemical corrosion.

All of these have been aimed at reducing maintenance effort as well as improving reliability. In spite of these improvements, corrosion and its control are very real problems that require a continuous preventive maintenance program.

Corrosion preventive maintenance includes the following special functions:

1. An adequate cleaning program.
2. Thorough periodic lubrication.
3. Detailed inspection for corrosion and failure of protective systems.
4. Prompt treatment of corrosion and touchup of damaged protective coating.

Inspection

Inspection for corrosion is a continuing problem and should be handled on a day-to-day basis. Overemphasizing a particular corrosion problem when it is discovered, and then forgetting about corrosion until the next crisis, is an unsafe, costly, and troublesome practice.

Most periodic maintenance requirement information has been placed on Maintenance Requirements Cards which are complete enough to cover all equipments in the aircraft. No equipment of the aircraft should go unchecked. Through experience, it will be learned that most equipments have trouble areas where corrosion will occur. Equipments in helicopters are particularly susceptible to corrosion due to the tactics in which the helicopters participate.

Protective Measures

An effective protection from corrosion requires the earliest possible repair of damaged protective coatings, including the removal of corrosion products and the restoration of corroded surfaces. This involves the maximum use

13571

of supplementary protective agents during any waiting periods or until such time as more positive protection can be restored. It must be a continuous program and recognized as a specific responsibility.

Periods of neglect or touchup maintenance, which may be necessaay under operating conditions, should be followed by a period of concentrated effort to correct any deficiencies which have started. A successful preventive maintenance program will tend to reduce the effects of severe service environments and the susceptibility of most aircraft and equipment to damage by these environments.

ANTICORROSION MATERIALS.– During manufacture, electronic equipments are usually sprayed with a protective coating that seals out moisture, thus preventing corrosion and fungus growth. In repair of these equipments, it is sometimes necessary to remove the protective coating by scraping or by the use of a solvent cleaner.

After making circuit repairs, the protective coating should be replaced. Rosin fluxes form coatings on solder connections that prevent oxidation during and after the soldering process, thus providing one form of replacement. A good general rule is that materials used should be those covered and controlled by military specifications, preferably those authorized specifically for use on aircraft. Use nonspecification materials only in emergencies, or where specific instructions so direct.

FUNGUS-RESISTANT MATERIALS.–Fungus susceptibility of materials has long been a serious problem, particularly with electronic equipments which may be subjected to extremes of humidity under tropical temperatures. While the fungus itself is objectionable since it generally "fouls" all types of equipment, its most serious effect is the increased possibility of shorting and arcing because of its moisture content.

The fungus problem has been further aggravated in the past decade by the increased use of a large number of organic materials in equipment used by the Navy. These materials vary in nature and size from large sheets of reinforced plastic for structural components to special dielectric substances used in complex electronic gear.

Fungus removal generally follows the same procedures of corrosion removal.

CORROSION REMOVAL

In corrosion control, time is of the essence. Until the electrolyte is removed, the chemical reaction will continue. Although most of the electrolyte is removed, some will remain in inaccessible locations of the chassis or modules making the cleaning process particularly difficult.

When this occurs, the proper procedures and cleaning materials must be used. The remainder of this discussion will be devoted to the techniques and materials used in correcting this problem.

The extent of cleaning, using the following techniques, requires the decision of the Corrosion Control Officer assigned to the organization.

Dry Cleaning

When corrosion or salt crystals are discovered in a piece of equipment, as much of this as possible should be removed by dry methods. This entails breaking the solids from the metallic parts by wiping with a dry cloth or brushing with a stiff bristle brush. Care should be taken not to damage any of the components of the equipment.

Any loose residue should be removed by the use of low pressure dry air.

Although it may appear that all of the contamination has been removed, this generally is not the case. At this point a decision must be made as to the possibility of contamination existing in the inaccessible or undetectable areas of the equipment. If this decision indicates that contamination still remains in the equipment, then further steps must be taken in the form of liquid cleaning.

Fresh Water

Although immersion or flushing of electronic and other equipment in or with water violates previous training, fresh water is one of the agents used to remove salt water and deposits from equipments. After the equipment has been subjected to fresh water, the water

13572

must then be removed. This may be accomplished by dry air pressure, by the use of a spray (displacement) fluid, or by a drying oven.

DRY AIR PRESSURE.–If compressed air is not available, any type of compressor that will deliver clean dry air at 80 psi will be adequate to furnish air for spray cleaning and for blowing as much water as possible from the wet equipment before using the water-displacing fluid.

WATER-DISPLACING FLUID.–This fluid is generally available in pressurized aerosol cans or in drums and is called a spray-dry water-displacement composition. A paint spray gun or other spraying equipment for applying bulk water-displacing composition in a fine mist may be used if an aerosol-pressurized water-displacing composition is not available.

The equipment is sprayed with this composition, and then some means of drying such as heat oven, air pressure, or natural evaporation should be employed.

DRYING.–Forced draft ovens with accurate temperature control large enough to accommodate the equipment being cleaned are preferable for final drying of the cleaned equipment. If ovens are not available, a small room equipped with an exhaust fan and heaters can be used. The temperature in the drying facilities should be between 120° and 160° F, depending upon the temperature sensitivity of the equipment being dried. If a heated room is used for drying, its temperature should be at least 30° F above the ambient temperature.

Detergent

In some cases a detergent must be used. The detergent is available in aerosol type containers or in bulk form. Detergent is used because salt crystals have formed on the equipment or an oily deposit is present in the equipment. The detergent will dissolve the salt crystals and will also emulsify and suspend oil deposits in the solution. In either case, fresh water must be used to rinse the contaminated solution from the equipment.

Ultrasonic Tanks

An ultrasonic tank is a container for fresh water or a cleaning agent. The solution is vibrated either by a transducer or by forced air. The agitation helps remove particles from inaccessible areas of the electronic equipments. The frequency of the transducer is in the ultrasonic range (above 15 kilohertz) and accomplishes the cleaning in a much shorter period of time than the forced air. When equipment has been removed from an ultrasonic tank, the previously mentioned procedures for drying should be completed.

SALVAGE PROCEDURES

The following steps comprise the routine procedure for salvaging sea water contaminated electronic equipment:

1. Immediately after removal of the equipment from sea water contamination, the equipment should be flushed thoroughly with fresh water.
2. The equipment should be disassembled to units of a size that permits immersion in an ultrasonic bath and to allow better access of cleaning solutions.
3. Remove contamination with emulsion cleaning composition in the ultrasonic tank.
4. Rinse in an ultrasonic tank of fresh water or rinse with a fresh water spray.
5. Blow the rinse water from the equipment with clean compressed air and follow with an application of water displacing composition.
6. Dry in an oven or by natural evaporation.
7. Check for damage, repair and lubricate as required, then return to service.

Equipment which cannot be dismantled or is too large for cleaning in the ultrasonic tank can often be cleaned by spraying with a cleaning emulsion. Upon completion of the emulsion application, the equipment should be rinsed and dried as previously indicated.

CARE AND SERVICING

The operating quality, stability, and reliability of electronic equipment are strongly affected by the quantity and quality of maintenance. Shiny dials and polished handles may be impressive, but it is the care and upkeep of the equipment behind the front panel that determines the operational capabilities of an electronic system.

13573

13573

The minimum requirements for routine care and servicing are listed in the inspection requirements for aircraft and in the technical manuals for specific equipments. The discussion in this chapter is limited to specific items that present special problems or that require special techniques.

SPECIFICATIONS AND PROCEDURES

Detailed instructions, procedures, and specifications for the care, handling, stowage, and servicing of electronic items of equipment are contained in the Operation and Service Instruction Manual for each equipment and in the Maintenance Instructions Manual for each aircraft in which that item is installed. All such procedures must be followed exactly; the specifications must be closely observed. Some components, however possess certain characteristics which warrant special discussion in this context. It must be noted that many of the considerations listed in the following discussion as applying to specific components are, in fact, general considerations which apply to many other components as well.

SPECIAL COMPONENTS

The purpose of this discussion is to provide the information needed to handle magnetrons and other electron tubes properly and to understand why careful handling is necessary. Most of the information supplied may also be applied to other items of electronic equipage.

Magnetrons

Although magnetrons are usually large and heavy, and appear to be rugged, they are actually extremely delicate items. Many of the individual parts are very delicate, and they must remain in precise alinement if the magnetron is to operate properly. Jars, jolts, and vibrations can cause misalinement and render the magnetron useless. The magnet itself, although made of solid metal, can lose its magnetic strength if improperly stowed or handled, resulting in poor performance of the magnetron.

Manufacturers of magnetrons are required to package them according to very rigid specifications. The containers are designed to give the magnetron mechanical support to prevent crushing damage, resilient support to cushion it against shocks and vibrations, and a safe minimum distance from other magnets or ferromagnetic materials. (Magnets stowed close together or close to steel shelves, bulkheads, or other ferromagnetic objects will gradually lose their magnetic strength.)

A magnetron should be retained in its original container until needed for immediate installation. It should not be removed from its carton to conserve space and weight, but should be stowed in the complete container, regardless of the weight and space factors involved.

When unpacking a magnetron for immediate installation, all parts of the container–the outer and inner casings, the support brackets and braces, the mounting hardware, the plastic covers for receptacles and mechanical connectors, the cushion materials, etc.–should be retained for packing the magnetron removed from service.

Magnetrons which have been removed from service are often returned to the manufacturer or some other activity for analysis. These magnetrons must be treated in the same manner as when new–magnetrons damaged after removal from service cannot be analyzed for the cause of original failure. The container should be plainly marked to indicate that it contains a used tube.

Whenever a used magnetron is reshipped, it must be accompanied by all papers and records pertaining to its performance history, hours of operation, and reason for removal. Such paperwork is valuable in the analysis of the failure, and results in improved reliability of magnetrons.

The ceramic window and insulator are convenient places on which to make notations. Such markings form conduction paths which can cause arc-over; therefore, notations should never be made at these locations. (If notations are deemed necessary, use a tag tied at a convenient and acceptable location, or tacked to the outer container).

Magnetrons themselves are not sensitive to either high or low temperatures. However, to avoid possible damage from freezing, liquid-cooled magnetrons must be thoroughly drained and dried before repacking and stowage. If

the coolant does not contain an antifreeze, the magnetron should be flushed with ethylene glycol or alcohol before drying in case some liquid remains trapped in the cooling jacket. These steps should be taken any time a magnetron is repackaged, whether for reshipment or for stowage.

Electron Tubes

Electron tubes are generally considered among the most essential components in electronic equipment. Many types of receiving tubes have an expected useful life of 2,000 hours or more when used within their design limitations. Some types of transmitter tubes have similar life expectancies. However, many of the tubes used in airborne military equipment are not operated within design limitations, and therefore may have somewhat shortened life expectancies. Some of the more important factors which affect the actual useful life of electron tubes are discussed briefly in the following paragraphs.

Receiving tubes used in blocking oscillators, peaking or squaring amplifiers, or similar circuits are violently overdriven. It is reasonable to expect that such treatment may shorten the operating life of such tubes. On the other hand, operating a tube well below its power rating may be expected to lengthen its useful life. Thus it may be seen that the operation of the tube in its particular circuit application helps determine its operating life expectancy.

Filament burnout may be caused by repeated sudden application of full voltage to the filament. Since the initial surge of current through the cold filament is many times the rated operating current, initial heating of the filament is non-uniform. As a result, mechanical stresses due to thermal expansion are set up; these stresses weaken the filament structure and hasten its failure. In equipments where the filament power is switched on and off, these mechanical stresses may reasonably be expected to shorten tube life. In equipments where the filaments are left on and the plate voltages are switched, tubes should last longer.

In circuits where the filaments are frequently switched on and off, the tube elements expand and contract during the process of heating and cooling. The electrodes may soon begin to lean or sag, causing excessive noise loosened or broken elements, or microphonics to develop. While testing a circuit suspected of microphonics, an indication of loose elements or microphonics may be obtained by sharply tapping the tube while in operation, and noting the effects on the output indications. If the tube has no defects, there should be no appreciable change in the output indications.

Mechanical defects and increased gas within the tube may be due to faulty construction or to subsequent physical damage. Some manufacturing defects may not be detectable by standard testing methods until tubes have been in service for some time. Physical damage to a tube is usually the result of accidental abuse. It includes such factors as breakage, bent pins, loosened or detached tube parts due to excessive vibration or shock, leakage in the glass-metal seal, application of excessive voltage, etc.

Tubes with glass envelopes provide visible evidence of open filaments, excessive plate current, gas, or arcing. Metal-encased tubes may be felt to determine whether the filament is operating.

Changes in tube characteristics occur as a natural result of aging. Decreased emission results from deterioration of the cathode surface, formation of cathode interface surface in the tube, or decreased heating effeciency of the filament. Changes in cutoff voltage and in transconductance results from changes in the alinement of tube elements. Intermittent shorts are caused mainly by foreign matter, such as lint or loosened tube parts which are free to move within the tube assembly.

It has been found that by preoperating new tubes in a test rack prior to actual use, many early failures may be eliminated. For preoperation a steady current may be passed through the tube so that the plate and screen operate between one-half and full-rated dissipation. Such preoperation reveals short time changes of tube characteristics, improper emission, inherent mechanical defects, gassy conditions, warping or sagging of grid structures, poor welds, and cracked envelopes. Tubes which survive the first 100 to 300 hours with only minor changes in characteristics are considered good risks for several thousand hours of satisfactory operation in actual equipment.

13575

Tube defects contribute to many equipment failures. For this reason it is good practice for the technician, when troubleshooting equipment, to immediately eliminate any tube known to be faulty. Blind replacement of good tubes by new spares, however, should be avoided. Tubes that have operated for many hours with relatively stable characteristics are more reliable than new tubes just taken out of stock. In general, it is not advisable to replace all the tubes of a group after a predetermined number of hours without regard to their condition. In fact, if the tubes have operated satisfactorily for an appreciable length of time, the intervals between testing may be lengthened. However, certain tubes are notorious for having limited operating lives; in such cases periodic changing will prevent much trouble. The transmit-receive tube used in radar equipment is a good example of a tube that should be changed at regular intervals. In all cases, however, the procedure directed by higher authority must be followed.

CRYSTAL MATCHING

Many pulsed microwave equipments require matched sets of detector crystals for satisfactory operation. The matching of crystals may be accomplished under operating conditions, without elaborate calibration procedures, using normally available test equipment. In this discussion "matching" indicates that if the same amount of pulsed RF energy is applied to two or more detector crystals, the output pulses will not vary by more than a given ratio. If a given signal produces a 0.004-volt peak-to-peak pulse from one crystal and a 0.005-volt peak-to-peak pulse from a second crystal, the ratio is 5 to 4, or 1.2. Converting this to decibels,

$$20 \log 1.2 = 20\ (0.08) = 1.6 \text{ db}$$

Thus these crystals match within 1.6 db.

A practical method which is usable is indicated in figure 14-3. It is used to measure the calibrated power (supplied by the pulsed signal generator) required to produce a prescribed output (indicated on the oscilloscope). If two crystals require -15.5 dbm and -16 dbm, respectively, to produce a 0.004-volt peak-to-peak pulse, these crystals match within 0.5 db.

The signal generator used will depend on the frequency or frequencies where matching is desired. The crystal holder, bias source, and oscilloscope used will depend upon what is available and what crystals are being matched. Figure 14-3 (B) shows a bias source which may be locally made if a ready-built one (such as the AN/USA-7 unit No. 1) is not available.

TESTING

The term testing, as used in this section, refers to the use of associated equipment to determine or to evaluate the condition or quality of operation of a unit, circuit, or component. Proper testing procedures must begin with the selection of the test equipment. This equipment must be used according to specific instructions. The testing must follow detailed procedures. The results must be evaluated in light of itemized specifications.

The following paragraphs discuss some aspects of the selection of proper test equipment, followed by some special considerations in the testing of certain circuits and components.

SELECTION OF TEST EQUIPMENT

The first requirement of any test equipment is its ability to perform the test required; secondly, it must be compatible with the equipment under test. Chapter 8 of this manual is devoted to a discussion of test equipment. The present discussion is confined to the compatibility between test equipment and the equipment under test, followed by some factors regarding the evaluation of the results of certain tests.

Impedance Matching

Closely associated with circuit loading is the idea of impedance matching. As it pertains to test equipment usage, impedance matching involves the reactive components as well as the resistive component of circuit impedance. For a maximum transfer of power the resistance of the source must equal the resistance of the load and the reactive components must cancel. However, in many testing situations this condition is undesirable.

13576

Figure 14-3.–Crystal matching procedure.

Most items of electronic and test equipment are rated according to input and/or output impedances. Coaxial cables and coaxial adapters are usually supplied with test sets normally used in testing of electronics equipment. The test procedures which govern the use of a specific equipment for a specific test on a specific equipment contain itemized lists of the items required. Use of the specified items provides adequate impedance matching.

As mentioned previously, the cables and fittings supplied with a given test set should be used with that set–substitution of cables frequently causes mismatching of impedance and results in erroneous test results.

Frequency

Another important consideration in the selection of test equipment involves the respective frequency ranges of the test set and the equipment under test. Signal generators must supply frequencies within the response band of tuned circuits; frequency meters must be responsive to the frequencies in the outputs of tuned circuits.

Amplitude

The output signal magnitude of the generator must be large enough to cause a response in

OBJECTIVE: To learn how to visualize objects.

RELATED INFORMATION:

If a draftsman hopes to be successful, he must be able to determine the number of views needed to produce a satisfactory and easily read drawing. This is one of his prime functions on the job. In drawing, the draftsman is confronted with objects which have three distinct types of surfaces, namely: (1) regular, (2) inclined plane, (3) curved surfaces.

We will first discuss objects which have regular surfaces. Surfaces of such objects are vertical and horizontal planes. The regular-surface object in Fig. 1 is shown as a pictorial (or 3-dimensional drawing) at the top and as an orthographic projection (or 2-dimensional drawing) underneath. Considering only the orthographic projection, the front view of the three-view drawing is the most descriptive of the object's shape. The top view is placed, or projected, directly above the front view, while the side view is directly beside the front view. This arrangement of views must always be observed for all two-dimensional drawings. The side view may be either left or right of the front view, and it is also possible in rare cases to show a bottom view directly below the front view if it is felt that this view will allow the drawing to be better visualized by the reader.

FIG. 1

the circuit under test. To test the output of that circuit, the test set must have sufficient sensitivity to respond to the signal. In either case, however, signal amplitude must not be so large that it overdrives or damages the equipment. If signals are too large, reduced coupling or increased attenuation may be used to reduce its size. This change must be considered in any evaluation of the test.

Polarity

Many nonsinusoidal signals are used in electronics equipment. Test equipment used in checking circuit operation must be capable of generating (or responding to) the proper polarity input. An example of this requirement is found in the triggering signals of radar synchronizers. Signals having the wrong polarity fail to activate the triggered circuit, and may erroneously indicate a malfunctioning circuit.

CIRCUITS AND COMPONENTS

The most frequently encountered areas of testing are concerned with tubes, tuned circuits, and power measurements.

Testing of Electron Tubes

As previously mentioned, tubes cause more than 50 percent of all electronic equipment failures. The condition of a tube can be determined by substituting a tube known to be good for the questionable one. However, indiscriminate substitution of tubes is to be avoided, as detuning of circuits may result. In addition, a tube may not operate properly in a high frequency circuit, although it performs well in a low frequency circuit. Therefore, in order to service electronic equipment, a knowledge of tube testing devices and their limitations, as well as correct interpretation of the test results obtained, is indispensable for accurate and rapid job performance.

In order to determine the condition of an electron tube, some method of testing is necessary. The operating capabilities (and design features) of a tube are shown by its electrical characteristics. A tube is tested by measuring its characteristics and comparing them with representative values established as standard for that type of tube. Tubes which read abnormally high or low with respect to the standard are subject to suspicion. Practical considerations take into account the limitations of the tube test in predicting actual tube performance in a particular circuit. For most applications the testing of a single tube characteristic is enough to determine whether a tube is performing satisfactorily.

Testing the emission characteristic of the cathode or filament is perhaps the simplest method of determining the condition of a tube. Since emission normally decreases as the tube ages, low emission is normally indicative of the end of tube serviceability. This test is subject to limitations because it tests the tube under static conditions and does not consider the actual circuit operation of the tube. Furthermore, coated cathodes or filaments may develop highly emissive spots, so that the relatively small grid area adjacent to these spots cannot control the electron stream. Under these conditions, testing the total emission may indicate the tube to be satisfactory, while in reality it is defective.

The transconductance (Gm) of a tube used in an amplifier stage is normally a more useful characteristic to measure than the emission. Transconductance is the change of plate current which results from a change in grid voltage. This characteristic, therefore, indicates the ability of the tube to amplify a-c signals. The most common military tube testers provide dynamic transconductance measurements, although some of the testers are limited to static measurements of this characteristic.

It should be kept in mind that a tube-testing device only compares the characteristic of a given tube with a standard for that particular type of tube. Since the operating conditions imposed upon a tube may vary over wide limits, it is not possible for the tube tester to evaluate a tube in terms of performance capability for all applications. Therefore, the tube tester is not always considered the final authority in deciding whether or not a tube is satisfactory. Substituting a good tube in the equipment, and observing the performance of the equipment, provides the most reliable evidence concerning the condition of the tube in question. Substitution is also the only method for testing many high power tubes used for transmitter applications.

13578

Nevertheless, the tube tester plays a very important function in most cases because it provides a quick and satisfactory check on tube serviceability.

Alinement of Tuned Circuits

Tuned amplifier, oscillator, detector, and filter circuits must be properly adjusted for optimum performance of communication and electronic equipment. The signal generator, in conjunction with various indicating devices, is used for most alinement procedures in receiving equipment. Transmitter oscillators can be tuned to the correct frequency by frequency measuring instruments, and transmitter amplifier stages can be adjusted by means of output meters or grid and plate current measurements. However, it is sometimes advantageous to tune transmitter amplifier stages by injecting a known signal from a signal generator in the same manner that receiver amplifier stages are tuned. The type of test equipment necessary for a particular tuning procedure is determined by frequency, power level, accuracy, allowable distortion, and modulation requirements.

The principal purpose of a signal generator is to provide a known signal with adjustable characteristics. There is need, on occasion, for square or other nonsinusoidal waveforms; however, in general, test procedures require the use of sine waves of variable frequency and amplitude.

The need for tuning electronic equipment may be indicated by reduced levels in signal outputs; however, alinement procedures should not be undertaken before general operating tests are made. Every equipment that is operating poorly requires maintenance, but it does not follow that every equipment that needs maintenance also needs alinement. Repairs which require the replacement of parts or the redressing of wiring may make subsequent alinement necessary. Therefore, no alinement should be attempted until all apparent troubles have been corrected and all defective parts replaced. Haphazard attempts at alinement by inexperienced or careless personnel may do more harm than good, and may increase the time required for making relatively minor repairs. Before alinement is attempted, all available instructions should be carefully consulted.

Power Measurement

One very common error in maintenance and in testing is the tendency to underestimate the meaning of decibel readings. As an example, test specifications for a particular portion of the testing procedure of a radar set might call for a decibel reading of 75 db. Upon performing the test in exactly the prescribed manner, it is determined that the decibel reading is 72 db. Too many technicians tend to assume that "this is good enough." It must be remembered, however, that a decrease (in power level) of 3 db represents a 50 percent reduction in power. This condition is intolerable when performing most tests.

SYSTEMS TESTING

Combinations of communication and electronic equipment and facilities are interconnected to form systems capable of performing specific functions. To meet reliability requirements and to comply with operating restrictions, technical personnel must be able to apply general test methods and practices to the installation, tuning, and maintenance of these combinations of equipment and facilities. This may entail a knowledge of many types of communication, and electronic equipment. Radar, communication and fire control equipment, when interconnected, may require different maintenance procedures than when operated separately. Revised test procedures may be necessary, any detrimental interactions between equipment or facilities must be corrected, and effective preventive maintenance must be programed for all equipment and facilities within the system. System quality figures, such as sensitivity and coverage, must be initially determined and measured during equipment preventive maintenance checks to assure efficient operation.

Receiver Sensitivity

The one measurement which provides maximum information about receiver condition in field operation is that of sensitivity. This measurement ordinarily requires the application of an input signal of variable voltage (which is accurately known by calibration) to the antenna terminals of the receiver, through an impedance which approximates that of the

13579

antenna with which the receiver is designed to be used. Any external impedance which is added to the signal-generator impedance to simulate the antenna impedance is usually known as a dummy antenna. It insures that the signal current in the input circuit of the receiver is the same as would appear with the known signal induced in an ideal receiving antenna, and it also insures that the input circuit of the receiver is "loaded" the same as it would be by an ideal antenna.

CONDITIONS FOR SENSITIVITY MEASUREMENT.–For measurement of sensitivity, the receiver is adjusted for the type of reception desired, and facilities such as tone controls or audio filters, AGC, silencer, noise limiter, etc., are placed in or out of operation as required or are set at appropriate control positions. The power-line voltage applied to the receiver should be well within the normal recommended operating range. The receiver output terminals should be properly loaded. At the headphone or audio-line terminals, unless otherwise specified in the instruction book for the equipment, the load should be a 600-ohm noninductive resistor (such as one of the composition type) capable of continuously dissipating the maximum receiver audio power output that can be produced at these terminals. High-impedance headphones may be used in shunt with the load for monitoring the output. Low-impedance phones may load the output appreciably and may have to be removed when data are being taken. The output voltage should be measured with a high-impedance audio voltmeter, capable of accurate indication from 0.1 volt to 100 volts, that will not appreciably load the output circuit. Although some receivers are equipped with audio-output meters, the meters provided may not indicate required standard noise levels with sufficient accuracy.

RECEIVER SENSITIVITY (AUDIO-OUTPUT) TESTS.–Receiver output power is measured, as part of a sensitivity test, to determine whether the receiver is performing according to the required sensitivity specifications. (The sensitivity is the value of signal voltage (in microvolts) fed to the antenna terminals that will produce a specified power output–usually 6 milliwatts–at the receiver output terminals with a signal-to-noise ratio of 10:1.) A simple way to check audio-power output is to use an a-c voltmeter (either a copper-oxide-rectifier type or an electronic voltmeter) across a resistor of the correct value, as specified in the instruction manual. With the signal generator delivering an input voltage to the receiver antenna terminals, the voltmeter measures the output voltage across the resistor. The power output is then computed by using the formula $P = E^2/R$.

Transmitter Power Output

Electrical power delivered to a load at any instant is equal to the product of the voltage across the load and the current passing through it, or P - EI. Under stable d-c conditions, this product is also equal to the average power consumed. In a-c circuits, on the other hand, the presence of either inductive or capacitive reactance means that the apparent power, EI, where both voltage and current are rms values, must be multiplied by a number called the power factor to obtain the true power. Briefly, this is necessary because pure inductors and capacitors store energy furnished by the line and, during a later portion of the cycle, restore such energy to the line. If purely reactive circuits were possible, none of the power would be dissipated. Naturally, resistance is an unavoidable component of any reactance, so from a strict standpoint nondissipative networks are not attainable. In practical a-c circuits, the power dissipated is equal to the apparent power multiplied by the cosine of the phase angle between the voltage and current.

Calibrated voltmeters and ammeters are used as a direct approach to power measurements in d-c circuits. Usually, approximate indications of power are satisfactory in electronic circuit work, so that neither the expense nor the inconvenience of two separate meters is justified. A typical instance is that of determining whether the power rating of a resistor is adequate. It is generally acceptable to measure the voltage across the resistor and then to calculate the power by the basic equation $P = E^2/R$. For current rather than voltage measurement, the power is equal to I^2R. If the designated resistance of the part is not sufficiently reliable, it may be measured approximately with an ohmmeter. Conceivably, an extremely accurate measurement may be

13580

required, in which case a determination by means of a Wheatstone bridge can be made. Similarly, it may be necessary to determine the a-c power dissipated by a resistive load, either at audiofrequency or radiofrequency. The same method is reliable, provided the resistance of the device is known at the frequency in question.

Power Supply Measurements and Adjustments

Power supplies that are commonly used in avionic equipment are either regulated or unregulated. An unregulated supply usually provides filtered but unregulated low B-plus (under 300 v d.c.) or high B-plus (over 300 v d.c.) in addition to a-c heater power for vacuum tubes and in some cases relay-operating power. The regulated power supplies consist of an unregulated supply and the associated circuitry necessary to regulate the B-plus output. Chapter 3 of Basic Electronics, NavPers 10087-B, contains a discussion of power supply operation.

Power supplies used to provide the d-c voltage sources for operation of electronic equipments are of various types, such as half-wave and full-wave rectifiers. The type circuitry employed for a particular application depends on such factors as current and voltage load requirements, available space, weight, degree of voltage regulation required, etc. Electronic systems are generally complex and contain one or more power supplies which provide several voltage outputs. The design performance of these equipments depends upon the proper operation of the power supplies. For this reason, power supply tests are included in the preventive maintenance test procedures prepared for most equipments. Many equipments are provided with easily accessible test points for ease in performing these tests. The more common type of power supply test is a simple voltage reading taken with the equipment in operation.

To operate radar equipment, various d-c voltages are required. The transmitter requires a high voltage source capable of delivering a large current for short intervals of time. The regulation or ripple content of this voltage is not critical. The cathoderay tube requires a high accelerating voltage which is usually easy to regulate because of the low current drain which results in a constant small load. The plate voltage supply for the receiver and the indicator sweep circuits require a source of good regulation and very little ripple. Voltages are also required for relays, blower motors, antenna control motors, etc. Combinations of vacuum tubes, rectifiers, vibrators, transformers, voltage dividers, etc., are used to provide these different voltages.

Power supplies of various types occur throughout the radar system because it is impractical to install all of them in a central location. Even though in some equipments the power supply may lose its identity as a separate unit, the function is still performed and must be tested and maintained at its rated performance.

Intermittent Troubles

Intermittent troubles are probably the most aggravating and irritating problem faced by the technician. The equipment always seems to be in proper operation while under observation, only to malfunction as soon as the technician turns his back. There is no single method for resolving this difficulty. The procedure to be used depends on the individual situation–the technician, the equipment, the available information, the peculiarities of the installation, etc. A thorough knowledge of the operation of the equipment, and an understanding of the most common causes of intermittent troubles should help to alleviate the suffering of the maintenance-man.

Some of the most common causes of intermittent troubles are loose vacuum tube elements, poor electrical connections, poor solder joints, leaky capacitors, arcing, broken terminal boards or printed circuit boards, fused conducting strips, and mechanical vibration. Vibration is usually associated with one or more of the others listed, either as a basic cause or as a contributing factor; therefore it should always be investigated early in the troubleshooting procedure. If the equipment seems to operate properly after a visual inspection fails to reveal the cause of the intermittent trouble, vibrate the equipment by tapping or jiggling while watching for indications of arcing, etc. If this fails to produce meaningful indications, methodical and patient troubleshooting procedures must be followed.

13581

13280

MISCELLANEOUS PROBLEMS

Generally, problems of the mechanical type are caused from excessive wear or carelessness on the part of the technician.

INSTALLATION OF EQUIPMENT

Although itemized installation procedures are listed in the Maintenance Instructions Manual for each model aircraft, and in the Operation and Service Instruction Manual for electronics equipment, this phase of the maintenance process presents a great deal of trouble. Most of the troubles in this category result from carelessness and oversight on the part of the technician. Specific instances are loose cable connections, switched cable terminations, improper bonding, lack of (or improper) safety wiring, remote switches in the wrong positions, failure to perform operational check after installation, failure to pressurize specified units, etc.

Two additional points concerning installation of equipment in aircraft need emphasis. Prior to reinstalling any unit or component, inspect its mounting for proper condition of shock mounts and bonding straps. After installation, safety wire as appropriate.

DISASSEMBLY AND REASSEMBLY

Problems are encountered in the removal and replacement of units in the aircraft and the disassembly and reassembly of subunits in the shop. Some of these problems are considered in this discussion. Most of these problems are created by the technician because of either carelessness or lack of understanding on his part.

One of the problem areas is the threaded fasteners used in the mounting of parts or subunits. Broken or stripped bolts, damaged heads or threads, etc., hamper the disassembly and reassembly process. The use of the proper tools and techniques are very important in keeping this problem to a minimum.

Some units that contain autotune systems that mechanically tune more than one subunit are a problem if these subunits are not properly alined mechanically before insertion into the autotune mechanism. If these subunits have mechanical stops and are inserted into the autotune system improperly, they can be damaged.

Pin or plug alinement before insertion into its mate is necessary if damage is to be prevented. Some of these pins are very small and delicate and will not withstand any bending or distortion without breaking. Some subunits or modules have different pin arrangements though their shell dimensions may be identical; therefore, great care must be taken to insure that the subunits or modules are installed in the proper location.

Coaxial connectors can also be a source of problems. When connecting or disconnecting these connectors, always use great care that the coaxial cable is not separated from the connector. Miniature coaxial connectors can be damaged very easily if handled roughly during connection or disconnection.

ROTATING EQUIPMENT

A great variety of rotating units are employed in naval aircraft. The electrically driven units are usually electric motors. In applications where only small movements are required, solenoids are frequently used (for example, ratchet stepping relays use solenoids).

Although the variety of rotating equipment is great, certain general maintenance procedures are common to the majority of them. Inspections are conducted on rotating equipment as a precaution against failure. Since most rotating units are installed in sections of the aircraft not accessible during flight, the first indication of trouble in many instances is complete failure. When failure occurs or when there are indications that the unit is operating improperly, remove the unit for shop inspection of bearings, commutator and sliprings, and brushes.

Bearings

Antifriction bearings are either ball or roller bearings. These, especially ball bearings, are widely used in aircraft rotating electrical machinery such as dynamotors, inverters, generators, and motor generators. In modern electrical machines, extensive use of sealed bearing assemblies is made. This makes mainte-

13582

nance and lubrication very easy since sealed bearings are prelubricated and require almost no attention during normal operation of the machine in which they are installed.

As a guide to proper maintenance of ball bearings in aircraft rotating equipment, the detailed recommendations of the manufacturer as given in the Service Instruction Manual should always be followed. Excessive lubrication leads to bearing trouble, and an undue amount of grease in the slipring or commutator compartment of the machine may result. Brush and slipring wear increases appreciably if a large amount of lubricant is present. Excessive lubricant should be removed with a cleaning solvent, and the bearings properly lubricated.

Commutators

The connection of the armature conductors to the individual commutator segments is made at the part of the segment referred to as the "riser." This connection is secured by use of hard solder or silver solder. Insulation of all segments from each other and from the armature shaft and core is accomplished by thin sections of mica between each segment and between the segments and the clamps which hold the segments to the shaft. The mica between the segments is cut to the same shape as the segments. That part of the mica directly under the brush is cut below the surface of the commutator bars.

When shop checking, insure that the commutator has a smooth, worn surface around the entire circumference throughout the area spanned by the brushes. It should have an even brown or chocolate color. Any dirt, oil, or grease on the commutator must be removed. Check for brush sparking as evidenced by rough and pitted commutator bars. Look for loose connections to the commutator risers. This may be indicated by specks of solder on the surrounding field coils and connections.

Should the commutator be dirty, it must be cleaned. Oil and dirt tend to glaze the surface with a high-resistance coating. Remove the brushes; blow loose dirt out with air, being careful not to blow it into the housing. Wipe oil and grease out with a lintless cloth moistened with an appropriate cleaning solution.

As the surface of the commutator gradually wears, the mica will eventually become flush with the brush surface of the segments. If this condition is not corrected by undercutting the mica, rapid brush wear is apt to result. Extreme care must be taken when undercutting to prevent the cutting tool from leaving the slot and scoring the brush surface of the commutator; also, great care must be exercised to avoid sharp edges on the commutator bars.

Brushes

The following checks should be made when checking the generator brushes and brush rigging:

1. Look for cracks in the brush holder yoke and check for tightness.
2. Check for loose screws and defective safety wires.
3. Check for loose brush holders and for dirt, grease, and oil.
4. Check for security of jumper leads between holders of like polarity.
5. Check to see that no brush holder is bent out of alinement.
6. Check for broken brush springs.
7. Check the freedom of the brush in the brush holder. The brush should not bind or drag in the holder, but neither should there be enough clearance that a sloppy fit is obtained.
8. Check all brushes for security of the pigtail to the brush and to the terminal, and see that the wire is not worn or frayed.
9. Check the brushes to see that they are not cracked or chipped. Check for pits due to sparking. Check for oil-soaked brushes. If the brush is oil soaked, it must be replaced. The oil acts as an insulator and terminal voltage is lowered.

When reinstalling the original brushes, make certain that they are replaced in their original holders; otherwise, it may be necessary to refit the brushes. When brushes are placed in their holders, the brush springs should be carefully lowered until they make contact with the brush. Never release the brush spring unless it is in contact with the brush since this allows the spring to strike the brush sharply, causing possible damage to the brush. Check for brush wear by measuring the length of the brush. It must be within the limits specified by the manufacturer.

13583

CAUTION: Brushes that have grease and oil on them must be replaced. They cannot be cleaned because a cleaning solvent will not remove all of the oil or grease and will change the electrical characteristics of the carbon. The brush holders and brush rigging should be cleaned before inserting the new brushes.

When it becomes necessary to install new brushes, the following procedure is recommended. Pull brush springs back only as far as necessary to allow removal of old brushes; this may be easily done by using a hook made of stiff wire. Attach brush pigtails of new brushes to proper connections and secure electrically. Insert brushes in brush holders. After the new brushes have been installed, steps must be taken to remove the old commutator film, fit the new brushes, and establish a new film.

For this purpose, a brush seater should be used. (Never use emery paper or any other kind of paper or cloth containing a metallic abrasive.)

The brush seater consists of a mildly abrasive material loosely bonded and formed in the shape of a stick about 5 inches in length. The brush seater is applied to the commutator while the machine is running, and therefore every precaution must be taken to prevent injury to the person applying it. The brush seater is applied lightly, for a second or two, exactly at the heel of each brush (fig. 14-4).

If the seater is placed even one-fourth inch away from the heel of the brush, only a small part of the abrasive will pass under the brush.

AT.277

Figure 14-4.–Using the brush seater.

Pressure is applied to the brush by setting the brush spring tension at maximum (during the seating operation) or by pressing a stick of insulating material against the brush. Dust is removed during the operation, and the machine is thoroughly cleaned afterwards.

Sliprings

Sliprings must be inspected periodically for smoothness of surface, diameter of the rings, and alinement of the rings on the shaft. The sliprings require the same careful attention as a commutator. Out-of-round conditions of the rings may be corrected in the same manner as for commutators, except for the fact that crocus cloth is used to apply a mirror-like finish following any turning or grinding operations.

13584

CHAPTER 15

DIGITAL COMPUTERS

Present and future technicians will be faced with a collection of electronic equipments which use computers as integral portions of the overall system. To understand the operation of the system in general, and the computer portion in particular, it is necessary to have a basic understanding of computer functions, circuitry, terminology, and applications. Basic Electronics, NavPers 10087-B, chapter 16, presents a basic coverage of the purpose, operation, and theory of computers, together with some of the terminology peculiar to them. Review and study of these basic coverages will aid in understanding the material covered in this chapter.

INTRODUCTION TO DIGITAL COMPUTERS

In the past few years, the term digital computer has appeared in Navy nomenclature. This term refers to an electromechanical device which is used in applications such as fire control, communications, and tactical data processing. Digital computers accomplish things that were impossible before, and they speed up processes which formerly required considerable time. Although the operations of computers are not new, the techniques of electronics have made possible a computer contained in a small, lightweight package which is adaptable to aircraft systems. Also, prior to the incorporation of electronics in digital computers, the great speed of operation required was impossible with purely mechanical devices.

The technician of today is faced with equipments which have the computer used as an integral part of the overall system. Therefore, the technician must have a basic understanding of computer functions, the circuitry involved, the numbering system used, and computer terminology.

The definition of a computer is: Any device capable of accepting information, applying mathematical operations to that information, and obtaining useful results of these operations. Therefore, a computer must have an input, processing, and output section.

Before any problem can be solved by a computer, the quantities involved must be expressed in terms of common units; that is, digital computation is the process in which digits alone are used to solve the problem.

Basically, the purpose of a digital computer is the same as that of any other computational aid. However, it is more accurate within practical limits of speed. Computers can perform thousands of repetitive computations involving hundreds of thousands of digits without making an error. Further, they can store millions of items of information for future use.

Digital computers also have limitations in that a continuous variable cannot be processed. Simple and explicit instructions (programing) must be provided for each operation that is to be performed. Instructions as to where information is stored, how to use it, what to do with it, and what step is required next are sometimes more complicated than the problems the computer is used to solve. Approximations and rounding off are also problems encountered with computers.

A digital computer performs its calculations by counting and comparing. With this simple capability, it can add, subtract, multiply, divide, and make logical decisions. Therefore, to perform computations with a digital computer, all that is needed is the provision of a method which will enable the machine to count, compare,

13585

13284

and transfer a digit from one place to another. Therefore, before a discussion of computer devices, it is necessary to learn the language of the computers.

NUMBERING SYSTEMS

While there are many different numbering systems, this discussion will deal with only two; that is, the base ten (decimal) and base two (binary) systems. The binary system will be compared with the decimal system because most computers utilize the binary system and most readers understand the decimal system. The bistable nature of simple electronic components such as switches (open or closed) and tubes and transistors (conducting or cutoff) makes the binary numbering system quite usable.

In the decimal system there are ten digits used (0 through 9), and in the binary system there are two digits used (0 and 1). The symbols or digits used are repeated as many times as desired or needed. Both systems also use the place value or positional notation concept. This means that a numeral has a specific value by virtue of its position.

An example of place value is shown in the two numbers 230 and 203. The 3 has a different value in each numeral by virtue of its position.

POSITIONAL NOTATION

In the previous example the numeral 230 when stated by the reader to be two hundred thirty, some assumptions are made which must be understood in order to compare the decimal and binary systems.

The first assumption the reader made was that when the number 230 was first looked upon, the number was assumed to be a decimal number. When no base symbol is given, the decimal system is assumed. If the number had been a base four number, it would have been written as $230_{(4)}$ with the 4 indicating the base of the numbering system. Some examples and their numbering base symbols are as follows:

Number	Base
398	ten (decimal)
$342_{(5)}$	five (quinary)
$101_{(2)}$	two (binary)

Therefore, when a number is written in base ten, no base indicator is given. If the number is written in a base other than ten, the base indicator is used.

Another assumption made is that the number 230 is two hundred thirty; that is, the digit 2 indicates hundreds, the digit 3 indicates tens, and the digit 0 indicates units. In base ten, this is true. The digits have specific values according to their position. Place value or positional notation for the number 378924 in the decimal system is as follows.

Place value	10^5	10^4	10^3	10^2	10^1	10^0
	100000	10000	1000	100	10	1
number	3	7	8	9	2	4

Notice that the place value column on the right is 10^0 or 1. The increasing place values, moving to the left, are indicated by the base (10) raised to one greater power. The second place value column is, then, 10^1, the third is 10^2, etc.

The number 378924, then, is

$$3(100000) + 7(10000) + 8(1000) + 9(100) + 2(10) + 4(1)$$

The place value columns for the binary (base two) system follow the same pattern as the base ten system except the base two is used.

For example, the number $10110_{(2)}$ is indicated in the place value chart for base two as follows:

Place value	2^4	2^3	2^2	2^1	2^0
	16	8	4	2	1
Number	1	0	1	1	0

The number $10110_{(2)}$, then, is

$$1(16) + 0(8) + 1(4) + 1(2) + 0(1) = 22_{(10)}$$

Notice that place value in base two has a different value than the same place in base ten.

COUNTING IN BASE TWO AND BASE TEN

In base ten, when counting from 0, the numbers are 0, 1, 2, 3, 4, 5, 6, 7, 8, 9.

13586

The next number to be counted is ten, but there is no single symbol in base ten to indicate the next number. Therefore, a combination of symbols is used by repeating the 0 and indicating a 1 in the tens column. This means one group of tens and no groups of units.

When counting in base two, there are only two digits or symbols; that is, 1 and 0. The same mechanical process is used in base two that was used in base ten. Starting with 0, in base two, the count is 0, 1.

There are no other symbols to indicate the next number so a 1 is written in the next place value column to the left and a 0 is written in the first place value column; that is, 0, 1, $10_{(2)}$.

This last number, then, indicates one group of two and no groups of units. The next number is $11_{(2)}$ which means one group of twos and one group of units. A number such as $1101_{(2)}$ would indicate one group of eights, one group of fours, no group of twos, and one group of units, and in this case is the same as decimal number 13.

Counting comparisons between the decimal and binary systems are made as follows:

Decimal	Binary
0	0
1	1
2	10
3	11
4	100
5	101
6	110
7	111
8	1000
9	1001
10	1010
11	1011
12	1100
13	1101
14	1110
15	1111
16	10000
17	10001

Notice that when counting objects, the decimal 17 and binary 10001 refer to the same object; therefore, decimal 17 must be equivalent to binary 10001.

CONVERSIONS

If the binary number 101 is to be converted to a decimal number, the binary number is written in expanded notation; that is

$$101_{(2)} = 1(4) + 0(2) + 1(1)$$

and the indicated multiplication, by terms, is carried out and yields

$$4 + 0 + 1 = 5$$

The 5 is a base ten number; that is, if objects were counted in a row and stopped with the decimal 5 and then the same objects were counted again in binary, the same object would be indicated with one-zero-one ($101_{(2)}$).

Example: Convert $11101_{(2)}$ to base ten.

Solution: Write $11101_{(2)}$ in expanded notation as

$$1(16) + 1(8) + 1(4) + 0(2) + 1(1)$$

and carry out the multiplication to obtain

$$16 + 8 + 4 + 0 + 1 = 29$$

Problems: Convert the following binary numbers to base ten.

1. 111
2. 1001
3. 11111
4. 1000001

Answers:

1. 7
2. 9
3. 31
4. 65

To convert the decimal number 26 to binary, first intuitively determine the largest place value column contained in the number; that is, in the place value chart

2^5	2^4	2^3	2^2	2^1	2^0
32	16	8	4	2	1

Objects that contain one or more plane surfaces which are neither horizontal nor vertical are known as inclined plane surfaces. The lightly shaded portion of the pictorial drawing in Fig. 2 represents an inclined plane. On the three-view (orthographic) drawing shown, the inclined plane is also represented by lightly shaded portions. In the front and top views, the inclined plane appears flat and similar to vertical or horizontal surfaces. In the side view in Fig. 2, however, the inclined plane is represented by the diagonal dashed line. Without this dashed line, the 3-view drawing could never be clearly read or understood.

PICTORIAL

FIG. 2

there is one group of 16 or 2^4 in 26. Also, there must be five digits in the representation of 26 in binary because the place value column for 2^4 is the fifth place value column from the right. This is indicated by drawing lines for each digit as follows:

2^4	2^3	2^2	2^1	2^0
—	—	—	—	—

There is one group of 16 in 26; therefore, write

2^4	2^3	2^2	2^1	2^0
1	—	—	—	—

Sixteen is indicated leaving 26 - 16 to be accounted for, or ten. There is one group of 2^3 in ten so write

2^4	2^3	2^2	2^1	2^0
1	1	—	—	—

After accounting for one group of 16 and one group of 8, 2 is left. There are no groups of 2^2 in 2 so write

2^4	2^3	2^2	2^1	2^0
1	1	0	—	—

and then find there is one group of 2^1 in 2 and write

2^4	2^3	2^2	2^1	2^0
1	1	0	1	—

leaving 0. Finally there is no group of 2^0 in 0 so write

2^4	2^3	2^2	2^1	2^0
1	1	0	1	0

Therefore, 26 in decimal is equal to 11010 in binary.

This type conversion is quite complicated in dealing with large numbers. There is a technique which enables us to convert from decimal to binary quite simply by continual division of the decimal number by the base of the binary system, indicating the remainder after each division operation until the quotient is zero. This is shown in the following:

Convert 26 decimal to binary–

```
2|26
  13     remainder is 0
2|13
   6     remainder is 1
2|6
   3     remainder is 0
2|3
   1     remainder is 1
2|1
   0     remainder is 1
```

The remainders are read from the bottom to the top to obtain the binary equivalent of the decimal number; that is;

$$26 = 11010_{(2)}$$

The division process may be combined as follows:

Convert 38 to binary–

```
2/38
2/19   0
2/9    1
2/4    1
2/2    0
2/1    0
  0    1
```

and the binary equivalent of 38 is $100110_{(2)}$.

Problems: Convert the following decimal numbers to binary.

1. 29
2. 624

Answers:

1. 11101
2. 1001110000

BINARY ARITHMETIC

Familiarity with the basic arithmetic operations in the binary system is needed in order to enhance the understanding of computers;

13588

therefore, a comparison between the decimal and binary systems will be discussed.

Addition

When counting in the decimal system, a limit is reached where the next number cannot be indicated in a single column; that is,

0
1
2
3
4
5
6
7
8
9

At this point a "carry" is made; that is, the first digit (0) is repeated and a 1 is indicated in the tens column. This means one group of tens and no groups of units, and is indicated by 10.

The ADDITION facts of the DECIMAL system are shown in the truth table below:

+	0	1	2	3	...
0	0	1	2	3	...
1	1	2	3	4	...
2	2	3	4	5	...
3	⋮	⋮	⋮	⋮	

for example:

+	0	1	2	3
0				↓
1				↓
2	→	→	→	5
3				

means

2 + 3 = 5

Binary addition is similar to decimal addition, except in binary only two digits, 0 and 1, are available. The mechanical procedure is the same.

The ADDITION facts of the BINARY system are as follows:

+	0	1
0	0	1
1	1	10

That is,

+	0	
0	0	

means

0 + 0 = 0

and

+		1
0		1

means

0 + 1 = 1

or

1 + 0 = 1

and

+	0	
1	1	

means

1 + 0 = 1

13589

or

$$0 + 1 = 1$$

and

+		1
1		10

means

$$1 + 1 = 10$$

This means that

$$0 + 0 = 0$$
$$0 + 1 = 1$$
$$1 + 0 = 1$$
$$1 + 1 = 10$$

When adding numbers in base ten, the following mechanical procedure is followed:
Add 172 and 32

```
  172
+  32
  104 partial sum
 +100 carry overs
  204 final sum
```

When adding two binary numbers, the process is

```
  0101
 +0111
  0010 partial sum
 +1010 carry overs
  1000 partial sum
 +0100 carry overs
  1100 final sum
```

The previous addition may be stated as follows:

Starting from the right column, one plus one equals 0 and 1 carry. The carry plus zero plus one equals zero and one carry. The carry plus one plus one equals one and one carry. The carry plus zero plus zero equals one.

Problems: Add the following binary numbers.

1. 1001 and 101
2. 1101 and 1111

Answers:

1. 1110
2. 11100

Computer Addition

The computer technique of addition utilizes the process of half add, carry, and final sum. Half add means to add two digits and neglect the carry. The carry is written below the half add sum and then added to this half add sum. An example in decimal is as follows:
Add 3562 and 2149

```
  3562
 +2149
  5601  half add
 +0110  carry overs
  5711  final sum
```

If other carry overs are required, they are handled as follows:
Add 4965 and 5247

```
  4965
 + 5247
  9102  half add
 + 1110  carry overs
  0212  half add
 +10000  carry overs
 10212  final sum
```

Problem: Add the following, indicating half adds and final sums.

1. 9328 and 6973
2. 9323 and 739

Answers:

1. 5291 half add
   16201 half add
   16301 final sum
2. 9052 half add
   0062 half add
   10062 final sum

The computer technique is used in binary as it is used in decimal.

Example: Add the binary numbers 11101 and 1101.

13590

Solution:

```
   11101
+   1101
   10000  half add
+  11010  carry overs
   01010  half add
+100000   carry overs
  101010  final sum
```

Example: Add the binary numbers 1101 and 110.

Solution.

```
    1101
+    110
    1011  half add
+   1000  carry over
    0011  half add
+  10000  carry over
   10011  final sum
```

Problems: Add the following binary numbers indicating half adds and final sums.

1. 110 and 10
2. 11011 and 111

Answers:

1. 100 half add
   000 half add
   1000 final
2. 11100 half add
   11010 half add
   10010 half add
   00010 half add
   100010 final sum

Subtraction

Both the direct and complement method of subtraction will be discussed. The methods will also be compared in the decimal and binary systems.

DIRECT SUBTRACTION.–In the decimal system, when subtractions are made, the terms to be subtracted are named as follows:

```
 7  minuend
-2  subtrahend
 5  difference
```

In cases where the subtrahend, in a particular column, is greater than the minuend, a borrow must be made; that is, a digit must be moved from a higher place value column to a lower place value column. An example is

```
 76
-39
```

where 9 is to be subtracted from 6.

In this case one group of tens must be borrowed from the 7 group of tens. This is shown by

```
 76
-39
```

is

```
   10
 6  6
-3  9
```

and 9 from 16 is 7. Therefore,

```
 6 16
-3  9
  37
```

This concept may be applied to as many columns as necessary. For example, in the problem

```
 9326
-7438
```

one group of tens is borrowed from the two groups to give

```
     10
 931  6
-743  8
    8
```

then one group of hundreds is borrowed from the three groups to give

```
     10 10
 92  1  6
-74  3  8
    8  8
```

13591

The next step is

```
  10 10 10
   8 2  1  6
  -7 4  3  8
  ----------
   8  8  8
```

and finally

```
  10 10 10
   8 2  1  6
  -7 4  3  8
  ----------
   1 8  8  8
```

The subtraction problem difference may be verified by adding the difference to the subtrahend to give the minuend. This shown by

```
  1888
 +7438
 ----
  9326
```

Binary subtraction problems are solved in the same manner as decimal subtraction problems except base two is used. One fact may cause problems; that is, when 1 is subtracted from 0, the difference is 1 if a borrow of 1 is made. An example of this is shown by the following:

```
  10
 - 1
 ---
```

A borrow of 1 is made, to give

```
  10
  0 0
 - 1
 ---
```

10 (which must be read as "one-zero," and not as "ten") in base two is really 2 in decimal, and 1 from 2 is 1. Therefore,

```
  10
  0 0
 - 1
 ---
   1
```

When no 1 is available in the next higher place value column, a higher place value column must be used. This is shown in the following example of binary subtraction:

```
  100
 - 1
 ---
```

A borrow from the 2^2 column is made, giving 10 in the 2^1 column.

```
   10
  0 0 0
 -   1
 -----
```

Then, a borrow of 1 is made from the 10 in the 2^1 column, leaving 1 in this column and giving a 10 in the 2^0 column, and 10 minus 1 is 1,

```
   10
  0 1 0
 -   1
 -----
```

Therefore,

```
   10
  0 1 0   minuend
 -   1    subtrahend
 -------
  0 1 1   difference
```

Verification of this difference is made by adding the subtrahend to the difference to yield the minuend.

```
  011
 + 1
 ---
  100
```

Problems: Find the difference in the following binary subtraction problems.

```
1.  101        2.  10101
   - 10           - 111
   -----          -----
```

Answers:

1. 11 2. 1110

SUBRACTION BY COMPLEMENTS (BASE TEN).–Digital computers are generally unable to perform subtraction in the manner previously discussed because the process of borrow involves operations which are impractical to incorporate into a machine. The process which involves complements is used in digital computers. By complement, it is meant the number

13592

or quantity required to fill or complete something. The complement of a number is, therefore, another number which completes the original number with respect to a known reference.

For example, the nines complement of a number is that number when added to the original number that will yield all nines in the place value columns used. An example of this is as follows:

What is the nines complement of 32?

What number, when added to 32, will produce 99?

Intuitively, it can be seen that the number is

$$99 - 32$$

or

$$67$$

If one is now added to the nines complement, the tens complement results; that is,

$$67 + 1 = 68$$

and 68 is the tens complement of 32. Notice that if 68 is added to 32, the sum is 100. Therefore, the tens complement of a number is defined as that number which, when added to the original number, yields a 1 in the next high place value column and zeros in all other columns. The tens complement of 78 is

$$100 - 78 = 22$$

Notice that the tens complement is in reference to a power of ten one place value higher than the highest place value of the original number.

Number	Tens complement	Reference
7	3	10^1
21	79	10^2
309	691	10^3

Rather than subtract the subtrahend from the minuend, the tens complement of the subtrahend (found with reference to the power of ten one place value higher than either the subtrahend or minuend) may be added to the minuend and then decrease this sum by the reference power of ten used to obtain the difference. A step-by-step process is shown to explain the preceding statement.

Example: Subtract 26 from 49

Solution: Write

$$\begin{array}{r} 49 \\ \underline{-26} \end{array}$$

then find the tens complement of 26 which is

$$100 - 26 = 74$$

This may be rearranged as follows:

$$100 - 74 = 26$$

Now, instead of writing

$$49 - 26$$

write

$$\begin{aligned} & 49 - (100 - 74) \\ = {} & 49 - 100 + 74 \\ = {} & 49 + 74 - 100 \\ = {} & 23 \end{aligned}$$

This indicates that the minuend (49) plus the tens complement of 26 (that is, 74) are added, then the reference power of ten used (100) is subtracted to give the difference which is 23. Notice that

$$\begin{aligned} & 49 - 26 \\ = {} & 49 + 74 - 100 \\ = {} & 123 - 100 \\ = {} & 23 \end{aligned}$$

the digit (1) found in the place value column higher than the highest place value column of the subtrahend had only to be dropped. Generally, this digit (1) which is developed indicates the difference (23) is a positive value.

Example: Subtract 36 from 429

Solution: Write

$$\begin{array}{rl} 429 & \text{minuend} \\ -\ 36 & \text{subtrahend} \end{array}$$

then

13593

13295

```
   429 minuend
 + 964 tens complement of subtrahend
 1|393
 =+|393 remainder
```

The process of subtracting a larger number from a smaller number, using the tens complement, is slightly different from the example previously shown. Instead of developing a 1 in the higher place value column, a zero will be present. The complement of the apparent remainder will indicate the actual negative remainder.

Example: Subtract 362 from 127

Solution: Write

```
   127 minuend
 - 362 subtrahend
```

then

```
   127 minuend
 + 638 tens complement of
       subtrahend
 0|765 apparent remainder
 =-|235 tens complement of apparent
       remainder
```

which is

```
 - 235 actual negative remainder
```

SUBTRACTION BY COMPLEMENTS (BASE TWO).–Digital computers use the complementary addition technique for subtraction, which has been discussed in decimal notation; and they also use the base two system. The process for base two is similar to base ten.

The ones complement of a binary number is that number with all 1 digits changed to 0's and all the 0 digits changed to 1's. This process is termed inversion. Therefore, the ones complement of 10110 is 01001. The twos complement of a binary number is its ones complement plus 1; that is,

Number	Ones complement	Twos complement
01	10	11
111	000	001
1110	0001	0010

Notice that the number 01 plus its twos complement 11 equals 100 which is a 1 in the next higher place value column followed by zeros.

The twos complement may also be determined by inverting every digit after the first one (1); that is, starting with the smallest place value and moving toward the largest place value (right to left). This method is normally less time consuming than determining the ones complement and then adding one to form the twos complement. For example: the twos complement of

```
      001101011|10     The first one (from
    ←invert all|        right to left) does
is              |       not invert.
      110010100|10
```

This indicates that the same procedure used for decimal numbers may be used for binary numbers to perform subtraction by the addition of the complement.

Problems: Find the ones and twos complements of the following binary numbers.

1. 101
2. 101101

Answers:

	Ones complement	Twos complement
1.	010	011
2.	010010	010011

Example: Subtract the binary number 01101 from the binary number 11001.

Solution: Write

```
 11001 minuend
 - 01101 subtrahend
```

then

```
   11001 minuend
 + 10011 twos complement of the subtrahend
 1|01100 difference
 =+|01100 positive difference
```

Notice that the same number of place value columns must be used in both the subtrahend and minuend.

Example: In binary, subtract 1110 from 1111.

13594

Solution: Write

```
  1111  minuend
- 1110  subtrahend
```

then

```
  1111  minuend
+ 0010  twos complement of the subtrahend
  1|0001  difference
= +|0001  positive difference
```

As in the decimal system, if a one is developed, it indicates plus. If a zero is present, it indicates a negative apparent answer and the complement of the apparent answer is used, preceded by a minus sign.

Example: In binary, subtract 1011 from 1001.

Solution: Write

```
  1001  minuend
- 1011  subtrahend
```

then

```
  1001  minuend
+ 0101  twos complement of the subtrahend
  0|1110  apparent difference
- |0010  twos complement of the apparent
        difference
= -|0010  negative difference
```

Problem: Subtract in binary, using complementary addition.

1. 1101 from 1110
2. 111 from 10

Answers:

1. +0001
2. -101

A verification of the preceding problems may be made by changing the binary numbers to decimal, carrying out the subtraction, then changing the difference back to binary.

This is as follows:

	binary		decimal
1.	1101	=	13
	1110	=	14

and

$$14 - 13 = 1 = 1_{(2)}$$

	binary		decimal
2.	111	=	7
	10	=	2

and

$$2 - 7 = -5 = 101_{(2)}$$

Multiplication

The direct method of multiplication of decimal numbers is shown in the following example.

Example: Multiply 32 x 25

Solution: Write

$$25 = 20 + 5$$

then

$$32\ (20 + 5)$$

Using the distributive principle

$$\begin{aligned} &32\ (20 + 5) \\ &= 32\ (20) + 32\ (5) \\ &= 640 + 160 \\ &= 800 \end{aligned}$$

The same problem written as

```
  32
x 25
```

gives

32 x 5
= 160 partial product

and

32 x 20
= 640 partial product

then

160 + 640
= 800 product

The technique generally used is

```
   32
 x 25
  160
 64
  800
```

Notice that the 64 really represents 640, but the zero is omitted.

Direct binary multiplication uses the same technique as direct decimal multiplication.

Example: Multiply the following binary numbers.

110 and 1101

Solution: Write

```
   1101
 x  110
   0000
  1101
 1101
1001110
```

This may be verified by changing the factors to decimal, multiplying and obtaining the decimal product, then changing the decimal product back to binary.

Problems: Multiply the following pairs of binary numbers.

1. 11 and 101
2. 11011 and 1011

Answers:

1. 1111
2. 100101001

Repetitive Addition

The idea that multiplication is repetitive addition is of beneficial use when working with computers. When multiplication is to be accomplished with a computer, the process of repeated addition is used.

If two numbers are to be multiplied together, write the following:

Multiply

231 by 45

Write

231 (40 + 5)

then

(231 x 40) + (231 x 5)

Multiplying each term gives the following:

```
  231        231
 x 40  and  x 5
 9240       1155
```

Notice that 231 could have been added forty (40) times to satisfy one half of the above problem and 231 could have been added five (5) times to satisfy the other half.

```
  231 ⎫                  231 ⎫
  231 ⎪                  231 ⎪
  231 ⎪                  231 ⎬ 5 times
  231 ⎪                      ⎪
   "  ⎬ 40 times          231 ⎪
   "  ⎪                + 231 ⎭
   "  ⎪                 1155
+ 231 ⎭
 9240
```

Rather than write 231 forty times, 2310 could have been written four times; that is,

```
  231 x 40
= 231 x 4 x 10
= 231 x 10 x 4
= 2310 x 4

= 2310
  2310
  2310
+ 2310
  9240
```

9240 + 1155 = 10395

When the repetitive addition type of multiplication is used in a computer, it would appear as follows. Two registers are used; that is, the accumulator and the multiplier. The accumulator maintains a constant subtotal and the

13596

multiplier keeps account of the addition to be performed.

The problem is to multiply 231 by 45.

Accumulator	Multiplier	
000000	45	These operations represent the five ones
+ 000231		
000231	44	
+ 000231		
000462	43	
+ 000231		
000693	42	
+ 000231		
000924	41	
+ 000231		
001155	40	These operations represent the four tens
+ 002310		
003465	30	
+ 002310		
005775	20	
+ 002310		
008085	10	
+ 002310		
0010395	00	

Notice that the multiplier indicated the number of times the number 231 was added and the accumulator maintained the subtotal. When the multiplier indicated 40, the 231 was changed to 2310 and the multiplier then would indicate addition of the 2310 four times. The overall effect was to move the zero in the 40 to the 231.

The binary system follows the previous techniques as shown in the following example. Multiply 1011 by 1101.

Accumulator	Multiplier
00000000	1101
+ 00001011	
00001011	1100
+ 00101100	
00110111	1000
+ 01011000	
10001111	0000

Division

The direct method of division of decimal numbers is shown in the following example:

Example: Divide 30 (dividend) by 5 (divisor).

Solution: Write

$$5\,\overline{)\,30}$$

Five is not contained in 3 but is contained in 30. How many 5's are contained in 30? The answer is 6, so write 6 above the zero

$$\begin{array}{r} 6 \text{ (quotient)} \\ 5\,\overline{)\,30} \end{array}$$

Multiply the 6 and 5 together and find the product which is 30. Write 30 under the 30 and subtract.

$$\begin{array}{r} 6 \\ 5\,\overline{)\,30} \\ \underline{30} \\ 0 \end{array}$$

There are no 5's in zero; therefore, the answer is 6.

Direct binary division follows the same procedure.

Example: Divide 1110 by 111.

Solution: Write

$$111\,\overline{)\,1110}$$

There is one 111 in 111 so write 1 above the right hand one in 111 as follows:

$$\begin{array}{r} 1 \\ 111\,\overline{)\,1110} \end{array}$$

Multiply 111 by 1 and write the product under the 111, and subtract, and bring down the last zero.

$$\begin{array}{r} 1 \\ 111\,\overline{)\,1110} \\ \underline{111} \\ 0000 \end{array}$$

There are no 111's in 0000; therefore, write zero after the 1 in the answer and find 10 is the answer.

13597

We have now seen that all lines represent edges which occur at the intersection of two surfaces of an object. In a top view of a rectangular table top, the lines would represent the intersection of the top surface of the table with its side surfaces. However, on curved surfaces, object lines are not always edge lines but are sometimes known as tangent lines. In Fig. 3 for example, the top horizontal line of the front view is a tangent line. It is not caused by the intersection of two surfaces but merely represents the top of the curved object.

FIG. 3

Much can be written about visualization, but the basic fact still remains that only through constant practice and study can you hope to achieve success in visualizing objects and then in drawing them.

ASSIGNMENT:

The following exercises are intended to increase your visual ability. Each figure shows a pictorial drawing and its corresponding orthographic projection. Place a number on each surface in the pictorial drawing, and the same number on the corresponding surface of the two-dimensional drawing, as shown on No. 1.

```
        10
111 / 1110
      111
        0
        0
```

Example: Divide 10010 by 110, all in binary.
Solution: Write

```
        1
110 / 10010
```

Multiply quotient and divisor and subtract from dividend.

```
        1
110 / 10010
      110
       11
```

Bring down last zero.

```
        1
110 / 10010
      110
      110
```

Find 110 goes into 110 one time and write

```
       11
110 / 10010
      110
      110
```

Multiply quotient and last dividend digit and find

```
       11
110 / 10010
      110
      110
      110
      000
```

and the answer is 11.

Problems: Divide the following binary numbers.

1. 10010 by 110
2. 10000111 by 101

Answers:

1. 11
2. 11011

Repetitive Subtraction

In multiplication, repeated addition is used; in division, repeated subtraction is used.

If one number (the dividend) is to be divided by another number (the divisor), write the following:

Divide 126 by 6
Write

```
126
- 6
120
- 6
114
- 6
108
- 6
"
"
```

Subtracting 6 from 126 twenty-one times registers a zero remainder.

A computer does the same thing except it utilizes powers of ten.

Use is still made of the accumulator and register as in repetitive addition but the technique is operated in reverse order.

Example: Divide 40320 by 126.

Accumulator	Quotient register	
40320		(a) Put the dividend in the accumulator.
	0000	(b) Set the register to zero.
-12600		(c) Put the divisor in the largest power of ten that is equal to or less than the value of the dividend that is in the accumulator.
	+0100	(d) Put the power of ten into the register.
27720		(e) Subtract.
	+0100	(f) Add the sums in the quotient register.

13598

Accumulator	Quotient register	
-12600	+0100	(g) Repeat steps (c), (d), (e), and (f) as shown.
15120	0200	
-12600	+0100	
2520	0300	
- 1260	+0010	
1260	0310	
- 1260	+0010	
0000	0320	Answer.

Example: Divide 126 by 6.

Accumulator	Quotient register	
126	000	
- 60	+010	
066	010	
- 60	+010	
006	020	
- 6	+001	
000	021	Answer

The same procedure applies to binary division except the highest power of 2 (in binary) is used.

Example: Divide 100111 by 11.

Accumulator	Quotient register	
100111	00000	
- 11000	+01000	Add 2^3 to quotient register.
1111	01000	
- 1100	+00100	Add 2^2 to quotient register.
11	01100	
- 11	+00001	Add 2^0 to quotient register.
0	01101	Answer

CODING

As stated previously, electronic circuit elements of computers are inherently binary; that is, they will have two stable states. Therefore, the base ten numbering system cannot be used efficiently in computers. While people communicate and calculate using letters of the alphabet and numbers of the decimal system, digital computers communicate and calculate using groups of binary symbols called codes.

Coding is the means by which data in one form is represented in another form which is acceptable to the computer. A form of coding is used in the Morse code in which letters are represented by dots and dashes. This makes the alphabet acceptable to transmission by radio.

Of the many coding systems, three of the most common ones are discussed. It should be understood that memorization of these codes is not necessary, but the understanding of the reasons for the codes is desirable.

BINARY CODED DECIMAL (B.C.D.)

This code makes use of groups of binary bits (binary symbols) to represent a decimal digit. In the decimal system there are only ten digits; therefore, only ten groups of binary bits must be remembered. EACH DECIMAL DIGIT IS REPRESENTED BY A GROUP OF FOUR BINARY BITS. The ten groups to remember are as follows:

Decimal digit	Binary - coded decimal digit			
0	0	0	0	0
1	0	0	0	1
2	0	0	1	0
3	0	0	1	1
4	0	1	0	0
5	0	1	0	1
6	0	1	1	0
7	0	1	1	1
8	1	0	0	0
9	1	0	0	1

To write ten in B.C.D., the use of two groups is required; that is,

Decimal	1	0
B.C.D.	0001	0000

Any two-digit decimal number requires two groups of B.C.D. etc.

Decimal	7	3	8
B.C.D.	0111	0011	1000

The separation of the B.C.D. groups is shown for ease of reading and does not neces-

13599

13238

sarily need to be written as shown; 738 could be written as 011100111000. One advantage of the B.C.D. over true binary is ease of determining the decimal value. This is shown as follows:

B.C.D.	0111	0011	1000
= decimal	7	3	8

738 in true binary is 1011100010

and, true binary 1011100010

$= \text{decimal } 1(2^9) + 0(2^8) + 1(2^7) + 1(2^6) + 1(2^5) + 0(2^4) + 0(2^3) + 0(2^2) + 1(2^1) + 0(2^0)$

$= 512 + 128 + 64 + 32 + 2 = 738$

The ease of converting from decimal to B.C.D. and from B.C.D. back to decimal should be apparent in the following.

Problems: Convert the following decimal numbers to B.C.D.

1. 7
2. 4200

Answers:

1. 0111
2. 0100001000000000

Problems: Convert the following B.C.D.'s to decimals.

1. 010000110001
2. 0101000001111000

Answers:

1. 431
2. 5078

The comparative ease of conversion in B.C.D. is related to the difficulty of conversion in true binary by the following.

Problems: Convert

1. 438 to binary
2. 100101101 to decimal

Answers:

1. 110110110
2. 301

One serious disadvantage of the B.C.D. is that this code cannot provide a decimal carry. The following examples are given to show this.

Example: Add the following:

Decimal		B.C.D.
5	=	0101
+ 3	=	0011
8	=	1000

Notice that there was no carry in the decimal addition and the answer in B.C.D. is equal to the answer in decimal. The B.C.D. is in correct notation and does exist.

Example: Add the following:

Decimal		B.C.D.
8	=	1000
+ 5	=	0101
13	=	1101

Notice that the B.C.D. answer is correct in true binary, but $1101_{(2)}$ does not exist in B.C.D. The correct B.C.D. answer for 13 should be 0001 0011. Therefore, when a carry is made in decimal, the B.C.D. cannot indicate the correct answer in B.C.D. form.

Excess Three Code

The excess three code is used to eliminate the inability of the binary carry. It is really a modification of the B.C.D. so that a carry can be made.

To change a B.C.D. number to excess three, add three to the B.C.D.; that is,

B.C.D.	1000
	+ 0011
Excess three	1011

In excess three code 1011 is 8 in decimal. The following chart shows the decimal, B.C.D., and the excess three code.

Decimal	B.C.D.	Excess three
0	0000	0011
1	0001	0100
2	0010	0101
3	0011	0110
4	0100	0111
5	0101	1000
6	0110	1001
7	0111	1010
8	1000	1011
9	1001	1100

As previously stated, the excess three code will provide the capability to carry in binary. The following is given for explanation.

13600 10381

Example: Add $6_{(10)}$ and $3_{(10)}$ in excess three.

Solution: Write

Decimal		Excess three with three groups possible
6	=	0011 0011 1001
+ 3	=	0011 0011 0110
9		

Notice that in group one the six and three are indicated. In groups two and three a zero (0011) in excess three is indicated.
Add as follows

0011	0011	1001	(Excess three)
0011	0011	0110	(Excess three)
0110	0110	1111	(Excess six)

But our answer is in excess six. Therefore, three must be subtracted from each group in order to return our answer to excess three.

0110	0110	1111	
-0011	-0011	-0011	
0011	0011	1100	(Excess three)
0	0	9	Answer in decimal

When a carry is developed in any group, the following procedure is used.

Example: Add $9_{(10)}$ and $3_{(10)}$ in excess three.

Solution: Write

Decimal	Excess three			
9	0011	0011	1100	(Excess 3)
+3	0011	0011	0110	(Excess 3)
12	0110	0111	0010	(Excess 6)

NOTE: Since group one created a carry, as shown, three must be added instead of subtracted in order to place group one into excess three. The other groups follow the previous example.

0110	0111	0010	(Excess six)
-0011	-0011	+0011	
0011	0100	0101	(Excess three)
0	1	2	

The above procedure will hold for any number of group indicators the computer possesses.

Problems: Add the following numbers using excess three and give the answers in excess three with three indicator groups.

1. 5 and 3
2. 4 and 3
3. 58 and 77

Answers:

1.	0011	0011	1011
2.	0011	0011	1010
3.	0100	0110	1000

A further advantage of excess three code is the ease with which the nines complement of a number indicated in excess three may be found; that is, the nines complement of 7, indicated in excess three as 1010, is found by inverting each digit in 1010 to read 0101. This 0101, in excess three, is 2 which is the nines complement of 7.

The following table shows the nines complement of the decimal digits:

Decimal	Excess three	Excess three inverted	Nines complement
0	0011	1100	9
1	0100	1011	8
2	0101	1010	7
3	0110	1001	6
4	0111	1000	5
5	1000	0111	4
6	1001	0110	3
7	1010	0101	2
8	1011	0100	1
9	1100	0011	0

GRAY CODE

This code is a modification of the binary counting system. In the Gray code sequence counting, only one bit will change as each count proceeds. When counting in binary from $7_{(10)}$ ($0111_{(2)}$) to $8_{(10)}$ ($1000_{(2)}$), notice that four bits had to be changed.

The Gray code is shown for comparison.

196 OF 327

ED

056 238

MICROCOPY RESOLUTION TEST CHART

NATIONAL BUREAU OF STANDARDS-1963-A

Decimal number	Pure binary	Gray code
0	0000	0000
1	0001	0001
2	0010	0011
3	0011	0010
4	0100	0110
5	0101	0111
6	0110	0101
7	0111	0100
8	1000	1100
9	1001	1101
10	1010	1111

In the Gray code when counting from $7_{(10)}$(0100) to $8_{(10)}$(1100), notice that only one bit changed.

One of the primary purposes of this code is the reduction of operational errors by changing only one digit at the time during the process of converting mechanical changes into numerical expressions. For example, to convert the shaft rotation (output of an analog computer) from seven to eight degrees would require only a change of one bit as previously indicated.

To convert a binary code to its Gray code equivalent, the following addition WITHOUT CARRY is used.

Example: Convert binary 0100 to its Gray code equivalent.

Solution: Keep the most significant bit as is.

Binary	0	1	0	0
Gray	0	—	—	—

Next, add horizontally the most significant bit to the next significant bit in the binary number and carry the sum to the Gray code as follows:

Binary	0	1	0	0
Gray	0	1	—	—

now add and continue as shown

Binary	0	1	0	0
Gray	0	1	1	—

then

Binary	0	1	0	0
Gray	0	1	1	0

Therefore, 0100 binary is equivalent to 0110 in the Gray code.

Example: Convert $14_{(10)}$ to Gray code.

Solution: Write

Decimal 14 = 1110 binary

Binary	1	1	1	0
Gray	1	—	—	—

then

Binary	1	1		
Gray	1	0		

add without the carry

then

Binary	1	1	1	0
Gray	1	0	0	—

then

Binary	1	1	1	0
Gray	1	0	0	1

therefore, 1110 binary is equivalent to 1001 in Gray code.

Problems: Convert the following decimal numbers to the Gray code.

NOTE: This transition must include the binary code.

1. 12
2. 35

Answers:

1. 1010
2. 110010

A method is also needed to convert Gray code to binary code.

Example: Convert 1101 in Gray code to binary.

Solution:

Gray	1	0	0	1	Retain the most significant
Binary	1	—	—	—	Gray code bit.
Gray	1	0	0	1	Add diagonally without a
Binary	1	1	—	—	carry.

13602

196

Gray 1 0 0 1 Continue diagonal addition.
Binary 1 1 1 _

Gray 1 0 0 1 Continue.
Binary 1 1 1 0 Therefore, Gray 1001 is equivalent to binary 1110.

Problems: Convert the following gray codes to binary.

1. 10000
2. 0001

Answers:

1. 11111
2. 0001

OCTAL NUMBERS

Octal numbers are base eight numbers; that is, there are only eight digits in base eight. These are 0, 1, 2, 3, 4, 5, 6, and 7. Because eight is a power of two, the octal system has special characteristics that make it especially useful in situations involving binary numbers. This is illustrated as follows:

A decimal number can be converted to octal by the same method described for decimal to binary; that is, to change 334 to octal write

	Remainder
8 / 334	
8 / 41	6
8 / 5	1
0	5

Therefore,

334 decimal = 516 octal or $516_{(8)}$

The same decimal number when changed to binary is 101001110.

Since things equal to the same thing are equal to each other

$$516_{(8)} = 101001110_{(2)}$$

Notice that the true binary number is separated into groups of three digits from the right as follows:

101 001 110

and by observation, notice that each group represents the following:

101 001 110
5 1 6

which is 516 in octal.

To convert from binary to octal, it is only necessary to divide the binary number into groups of three and read each group as the octal representation in place value.

To convert from octal to binary, the reverse operation is used; that is,

5 1 $6_{(8)}$
101 001 110

Example: Convert 40 decimal to octal, then to binary.

Solution: Write

	Remainder
8 / 40	
8 / 5	0
0	5

Therefore,

$$40_{(10)} = 50_{(8)}$$

and then

$50_{(8)}$
101 000

The preceding conversions from binary to octal and from octal to binary are possible because 2^3 is the same as 8^1.

Problems: Convert the following binary numbers to octal.

1. 101101
2. 1110110

Answers: (In base eight)

1. 55
2. 166

Problems: Convert the following octal numbers to binary.

1. 482
2. 761

Answers: (In binary)

13603

1. Impossible to have an 8 in base eight (is not an octal number).

2. 111110001

The octal number system affords many conveniences. When recording a binary number on paper, it is usually more convenient to write it in octal. For example, computer programers and programing manuals use the octal system as a convenient notation for binary numbers. Also, when converting a large decimal number to binary, it is usually more convenient to convert it to octal first and then to binary since fewer divisions are required in dividing a decimal number by 8 instead of 2.

A number in any base that is smaller than ten can be converted to a number in base ten (decimal) by the following method: Multiply the most significant digit (MSD) by the present (old) base, add the next MSD to the product of the last multiplication and multiply the sum by the present (old) base, continuing until the least significant digit (LSD) is added.

EXAMPLE: Convert
to decimal

INPUT AND OUTPUT DEVICES

An analog device yields an output in the form of a varying voltage, current, resistance, or mechanical shaft rotation. This form of output is unusable as an input to a digital computer. Since the majority of military indicating devices are of the analog type, their outputs must be converted to be used as inputs for the digital computers.

INPUT DEVICES

An input device is considered to be any device which yields an output which is usable for the particular computer it feeds. The devices which will be discussed are referred to as converters or encoders because they convert analog information into digital information.

V-Scan Converter

The V-scan converter continuously converts a changing mechanical position (analog information) into pulses (binary information) with an accuracy of plus or minus one bit (binary digit).

The basic method of converting a mechanical position into a binary code involves an arrangement of brushes and contacts. The mechanical movement positions the brushes relative to the contacts. The conducting contacts contain a voltage level which represents a binary 1 and the insulating contacts contain no voltage which represent a binary 0. The contact arrangement necessary to produce a natural binary code ranging from 0 to 15 is illustrated in figure 15-1.

NOTE: For the purpose of discussion, consider the contact arrangement in figure 15-1 as being attached on the side of a tank containing a liquid. The brushes are controlled by the level of the float which varies with the level of the liquid in the tank. Notice that, as shown, when the brushes move downward, a binary indication of the amount of liquid expended is indicated. The dark areas are conducting contacts and the light areas are insulating contacts. The four squares at the top of the contact arrangements represent four in-line brushes. The position of the in-line brushes, as shown, indicate a binary 0000 or zero. The analog output moves the brushes down the contacts to indicate any binary number from 0000 (zero) to 1111 (fifteen).

Unfortunately, there is an ambiguity associated with the use of the in-line brushes and the natural binary code. This problem arises at any point where two or more brushes are required to switch at the same moment from one type of contact to the other; that is, from conducting to insulating or from insulating to conducting.

Figure 15-2 shows a portion of a four-bit binary coding plate and reveals the exact nature of the problem. Note that the brush positions that are indicated by x's are reading a 6 (0110). At this instant the brushes are obviously providing the correct reading. Ex-

13604

AQ.195

Figure 15-1.–Natural binary code contact arrangement.

AQ.196

Figure 15-2.–Ambiguity with the natural binary code.

amination of the next position of the brushes, indicated by y's, however, reveals ambiguous readings. For this example, the brush position is at the switching point from 7 (0111) to 8 (1000). The brush in the 2^3 column is making contact with the conducting material, while brushes in the 2^0, 2^1, and 2^2 columns are still making contact with the conducting material. The output from the brushes at this time is 15 (1111), which should not occur when moving from 7 (0111) to 8 (1000). This produces an erroneous reading. Note that erroneous readings are also obtainable at the 9 to 10 switching point and at the 11 to 12 switching point.

Obviously, the possibility of reading a 15 when it should actually be switching from 7 to 8 (or reading 11 when it should be switching from 9 to 10, or of reading any of the other ambiguous numbers that may be produced) makes it impossible to read instantaneous values with any high degree of certainty. The major factors in determining the accuracy of the natural binary-coded converter are the positioning of the contacts, the positioning of the brushes, the size of the contacts, and the thickness of the brushes. The perfect converter, in order to preclude ambiguities, would have each contact exactly in its required position, all brushes in a straight line perpendicular to the direction of movement, all contacts exactly the same size, and the brushes infinitesimally narrow and exactly uniform. Meeting the prestated requirements for a perfect converter is a physical impossibility.

The V-scan converter employs a method of conversion whereby the physical requirements allow almost perfect conversion. This is accomplished by the use of a double brush (except for the 2^0 column brush) system. The particular relationship between the brushes is predetermined. The direction of movement to be used when describing one set of brushes as leading and one set of brushes as lagging is determined by the design of the grid. In figure 15-3 the direction which will determine the leading or lagging brushes is downward. This direction must be used regardless of whether the float is causing the brushes to move downward or upward. This may occur when filling or emptying the tank.

When reading the brush positions from right to left, two rules are followed:

1. If a bit is read as a one (electrical contacts touching) in a place value column, the

13605

AQ.197

Figure 15-3.–Natural binary code contact arrangement showing V-scan brushes.

next larger place value column is read on the lagging brush.

2. If a bit is read as a zero (nonconducting contact) in a place value column, the next larger place value column is read on the leading brush.

The determination of whether a leading or lagging brush is used at any particular time is a design function of this converter and will not be discussed.

Since the least significant digit (LSD) column has but one brush, it will always be the reference. As shown in each section of figure 15-3, there are some brushes that are touching conducting and nonconducting segments at the same time. By applying the previously stated rules, figure 15-3 (A) is read as follows:

Column 1: This is our reference brush and since it is conducting a binary 1 is read.

Column 2: Read the lagging brush position because column 1 brush was conducting. The lagging brush position indicates a zero.

Column 3: Read the leading brush position because column 2 brush was not conducting; therefore, a zero is read for column 3.

Column 4: Read the leading brush position which indicates a zero. Therefore, figure 15-3 (A) is indicating $1001_{(2)}$ or $9_{(10)}$.

The following sections of figure 15-3 indicate:

Figure 15-3 (B) - $0111_{(2)}$ or $7_{(10)}$

Figure 15-3 (C) - $1000_{(2)}$ or $8_{(10)}$

Figure 15-3 (D) - $1100_{(2)}$ or $12_{(10)}$

Figure 15-3 (E) - $1011_{(2)}$ or $11_{(10)}$

Figure 15-3 (F) - $1010_{(2)}$ or $10_{(10)}$

BINARY WHEEL.–The binary wheel is a basic application of converting shaft rotation (analog) to binary (digital) information.

The binary wheel is a plane comprised of concentric circles, with each ring divided into twice as many sectors as the adjoining inner ring. A close examination of figure 15-4 will show that it is really the previous rectangular set of contacts (fig. 15-2) set up in concentric rings. If the brushes are located in a straight line, as shown in figure 15-4, the same difficulty of erroneous indications will be present as the brushes move around the circles.

By installing dual brushes in all rings except the outer (least significant digit) ring, as shown in figure 15-5, and properly placing the brushes, the erroneous readings may be eliminated. The number indications are read as previously indicated for the V-scan readings. The direction of rotation of the disk determines which set of brushes will be leading or lagging–in this case, clockwise.

Binary Gray Coded Grid

Figure 15-6 shows a grid (coded in the Gray code) with five brushes. The shaded blocks indicate 1 binary, and the blank blocks indicate 0 binary. This is the same as previously used. Notice that as the brushes (x) more down the

AQ.198

Figure 15-4.–Simple five-bit shaft encoder.

AQ.199

Figure 15-5.–Five-bit V-scan encoder.

grid, only one brush will change its state (conducting to nonconducting or nonconducting to conducting) as the number is increased by one.

The brushes are shown to be indicating two in Gray binary; and as they move to 3 Gray binary, only one brush changed state. In figure 15-2 the movement from 7 to 8 caused an erroneous reading. Notice that as the brushes (y) shown in figure 15-6 move from 7 to 8, an erroneous reading does not occur because only one brush changed state.

BINARY GRAY CODED WHEEL.–Figure 15-7 shows the binary Gray coded wheel in which angular position of the brushes is represented by a Gray coded number. In changing from one number to the next, only one brush changes state. Notice that one set of brushes allows indications in sequential steps without ambiguous readings when moving from one number to the next.

In figure 15-7, the brush reading line shows the reading to be 01001 in Gray code. This indication could represent bearing, speed, direction, or any of many analog positions.

Brush Encoder Problems

The disadvantages of brush type encoders are early and frequent failures caused by excessive brush and disk wear, frequent miscounting, critical brush alinement, and low operating speeds. Brushes are susceptible to vibration and acceleration forces that can cause intermittent contact and shifts in brush position. High rotational speeds cause wear of the brushes and particle contamination of the code disk, which lead to a diminution of accuracy. Brush bounce at high speeds may be severe, resulting in extraneous pulse outputs. Although a compromise may be reached by an increase in brush-contact pressure, this also increases the load torque, aggravates the problem of wear of the brush contacts, and reduces life of the code wheel. The results are encoders which are unreliable, have a short useful life, require frequent and costly maintenance and/or replacement, and are limited in operating speed.

Optical Encoders

In optical encoders, there are no contacting surfaces other than bearings. Photocells are used to detect light from a light source through a code disk which has alternately opaque and transparent segments. Electronic amplifying, discriminator, and logic circuitry is required to optain the desired digital output. Continuous low-voltage d-c tungsten lamps are usually used as the light source, which has a predicted life of over 10,000 hours. The mean-time-between-failure (MTBF) of optical encoders is at least 10 times greater than that of comparable brush encoders.

OUTPUT DEVICES

Input and output devices are similar in operation but perform opposite functions. It is through the use of these devices that the computer is able to communicate.

Output information is also made available in three types: human information, such as codes or symbols presented on a cathode-ray screen which are used by the operator to answer questions or make decisions; information which operates a control device such as a lever, aileron, or actuator; or information which is stored in a machine language or human language, on tapes, or printed media.

Wheel Displays

Any one of the angle to number converters previously described can be connected as an output device, either to furnish an angle signal or display (pointer or servo signal) or to mechanically position a particular symbol on a wheel display. The symbol to be displayed can be any arbitrary number, letter, word, or other symbol selected by the designer.

The wheel can be positioned by a servomotor, by a step counting switch, by a digital to analog converter coupled with a motor, etc. The only limitation on the positioning system is that it must be able to drive the wheel until the correct symbol is displayed.

The display may be generated by wheels geared together in a fixed ratio (as in an odometer) or with each wheel individually driven and positioned. A disadvantage of the second system is the increased space required to accommodate the separate drive mechanisms. The number of symbols to be displayed is limited by the size of the wheel and by the number of discrete positions that can be selected.

13609

AQ.202

Figure 15-7.–Binary Gray coded wheel.

Practically any encoder can be used as a decoder (digital-to-analog converter) either directly or by positioning it with a null-seeking driver.

Lights

Each individual light may be considered as the equivalent of a binary stage: ON–true or one; OFF–false or zero. Lights are used to display such discrete data as failsafe, on-off, and warning. They may be used in groups and in conjunction with ring counters to form binary to decimal conversion displays. Each individual light is sequenced and illuminates the appropriate digit when switched on by the counters. (See fig. 15-8 (A).)

MULTIFILAMENT LIGHTS.–These lights may display numbers, letters, symbols, or combinations of these. Filaments may "edge light" lucite cards to illuminate engraved symbols, or may actually be shaped in the form of the symbol and glow when switched on. (See fig. 15-8 (B) and (C).)

Lights require appreciable current–greater than that which is normally available directly from the computing circuits. Therefore, a buffer or amplifier stage is usually required to furnish the additional current. Since a single display illuminates multiple symbols and requires at

13610

AQ.203

Figure 15-8.–Light displays.

least one terminal for each, it may require its own counter circuits to convert from binary code to the display code, or it may share a common converter with several other circuits. On the other hand, the individual filaments may be prewired to a printed circuit board, and the appropriate display selected and switched by computer circuitry.

The value or quantity being measured may be represented by a positioned display of multiple filament lights. The digital voltmeter is a fairly common example of the use of these lights.

APPLICATIONS

Digital computers are finding increasingly wide application in Navy aircraft. Some aircraft now operational, and others that will become operational in the near future, have computers installed as integral parts of the electronics system. Among the more common applications in Navy aircraft at present are the navigation systems, weapon delivery systems, tactical communications systems, ASW and ECM systems, and automatic flight systems.

The digital computer receives problems involving distinct and fixed numerical quantities, and produces the solution of these problems also as distinct and fixed quantities; that is, for a specific problem, the digital computer produces one specific answer which is based on the data supplied to the computer. If any factor in the problem is varied, it must then be treated as a new and different problem and the entire problem must be recomputed.

The digital computer expresses magnitude as a number of digits, and its accuracy is limited only by the number of significant figures provided. Increased accuracy can be obtained by utilizing more significant figures. The basic principle of operation of any digital computer is simply the process of counting.

The ability to make calculations is built into the computer by using appropriate combinations of relatively simple circuits. A computer also has the ability to retain information by storing it in memory banks. This information, fed to the computer by an operator, must be available whenever the operator calls for it.

When a computer performs an operation, it does so by comparing quantities representing data that have been placed into it. Its output consists of data that must be "read" and automatically translated into some form of understandable language.

There are two types of digital computers. The special purpose computer, designed to do a limited number of jobs, has a memory that is fixed (usually wired in). The general purpose computers, like the Univac, are capable of many jobs; but their circuitry, while fundamentally the same as that of the special purpose computer, becomes very complex when considered as a whole.

13611

Instructions are stored in the memory unit by a process called "readin." These instructions may be changed simply by reading in the desired new set of instructions. General purpose machines have great flexibility because of the ease with which the instructions may be changed; thus, they are able to do many jobs.

CHAPTER 16

COMMUNICATION FACILITIES, PRINCIPLES, AND EQUIPMENT

DISTRESS FREQUENCIES AND PROCEDURES

The assignment of radiofrequencies is an extremely important problem. Increasing use of the radiofrequency spectrum, by civilian as well as military communicators, means that the portions of the spectrum available for Navy use are limited.

Maximum economy in frequency usage is therefore essential and must be constantly exercised by assignment authorities. To prevent harmful interference, thorough coordination of frequency usage is essential. Coordination of frequency usage, by international agreement, is a responsibility of the constitutional authority of the governments concerned. In the case of active theaters of operations, however, this responsibility rests with the theater commander. In other areas where the national authorities consider it expediant, coordination of military assignments is normally undertaken by frequency coordination committees. Committees have been established in areas throughout the world to arrange for speedy and satisfactory coordination of frequency assignments with a minimum of interference.

The publication which outlines distress procedures and frequencies is Communications Instructions Distress and Rescue Procedure, ACP135 (current edition). This Allied Communication Publication (ACP) was developed for allied use. The sections of this ACP which are of particular interest to the technician are reviewed briefly in part in the following paragraphs.

INTERNATIONAL DISTRESS FREQUENCIES

The following list contains certain frequencies which are especially important:

1. 500 kHz–International Calling and Distress, preferably A2 (MCW) or B (damped wave) for aircraft, or survival craft using frequencies in the band from 405 kHz to 535 kHz when requesting assistance from the maritime services. It is used for the distress call, distress traffic, urgency signal, and safety signal.

2. 2182 kHz–Maritime Mobile Service Calling and Distress, for radiotelephone stations working in the authorized bands between 1605 kHz and 2850 kHz.

3. 8364 kHz–International Lifeboat, Liferaft, and Survival Craft, for operators equipped to transmit on frequencies between 4000 kHz and 23,000 kHz who wish to establish communications relating to search and rescue.

4. 121.5 MHz–International Aeronautical Emergency, for aircraft and those aeronautical stations primarily concerned with the safety and regulation of flights using national or international civil air routes and operating in the band between 118 MHz and 132 MHz.

Two frequencies, 121.5 MHz and 243.0 MHz, are distress and emergency frequencies for use by units of the services of nations equipped to operate in the VHF/UHF band. These frequencies are used only to provide a communications channel between airborne and ground stations, or between surface craft experiencing an actual emergency or distress condition. Other aircraft or surface units in the area can utilize these frequencies in taking immediate action to allevi-

13613

ate or avert the distress or emergency condition; however, these frequencies are not intended for communications incident to a coordinated search and rescue operation.

The first transmission by an aircraft is on the air/ground frequency in use. If the aircraft is unable to establish communications on this frequency, it should broadcast the distress or urgency call on the aeronautical emergency frequency or on any other frequency in an effort to establish contact. However, prior to changing frequency, and if time permits, the aircraft should transmit an appropriate phrase or "Q signal" indicating the frequency to which it intends to change.

A number of communication channels are required to execute the various phases of search and rescue operations and to communicate with aircraft in distress. These channels are listed as follows:

1. Control channel for the operation of search aircraft.

2. Control channel for the operation of search surface craft (including submarines).

NOTE: The frequencies for channels 1 and 2 above are assigned by the local Theater Commander or the local agency responsible for the assignment of frequencies.

3. Communication between survival craft and search aircraft and surface vessels (including submarines). For communication between the survival craft or ground survivors of an accident and ground search parties, search aircraft, search vessels and ground or air monitoring stations, assigned frequencies are 500 kHz, 2182 kHz, and 8364 kHz, 121.5 MHz, and 243.0 MHz.

4. Intercommunication channels between search aircraft and surface vessels (including submarines) are assigned the frequencies 3023.5 kHz, 5680 kHz, 121.6 MHz, 123.1 MHz, 138.78 MHz and 282.8 MHz. The use of 121.5 MHz is also authorized if necessary, but this frequency should be avoided, if at all possible, for search coordinating purposes.

The 123.1 MHz channel is intended for use inside the NATO European area, the 121.6 MHz channel for use in the United States and Canada, and the 138.786 MHz channel for use outside these areas.

DISTRESS PROCEDURES

Distress Signals

In radiotelegraphy, the distress signal consists of the letters SOS (di di dit dah dah dah di di dit) transmitted as a single signal ($\overline{SOS}$) in which the dashes must be emphasized so as to be clearly distinguishable from the dots.

In radiotelephony the distress signal consists of the word "MAYDAY," which is derived from the French expression "m'aider." These distress signals indicate that the ship, aircraft, or other vehicle sending the distress signal is threatened by grave or imminent danger and requests immediate assistance.

Alarm Signal

When the international distress frequency of 500 kHz is used, the distress call should, if practicable, be preceded by the alarm signal (twelve 4-second dashes, with intervals of 1 second between dashes) using A2 or B emission. If circumstances permit, the transmission of the full distress call should be separated from the end of the alarm signal by an interval of 2 minutes. The alarm signal should always be followed immediately by the distress signal, $\overline{SOS}$, sent three times, in order to operate automatic apparatus which may depend on the distress signal for activation.

Distress Call

The distress call and message are sent only on the authority of the person in command of the ship, aircraft, or other vehicle carrying the mobile station. The distress call has absolute priority over other transmissions. All stations which receive it must immediately cease any transmission capable of interfering with the distress traffic and must listen on the frequency used for the distress call. This call is not addressed to a particular station, and acknowledgement of receipt is not to be given before the distress message (see below) is sent.

The distress call transmitted by radiotelegraphy consists of:

1. The distress signal, transmitted three times.

2. The prosign DE.

13614

3. The call sign of the mobile station in distress, sent three times.

When the distress call is sent by radiotelephony it consists of:

1. The distress word MAYDAY, spoken three times.
2. The proword THIS IS.
3. The identification of the mobile station in distress, spoken three times.

Distress Message

The distress call must be followed as soon as possible by the distress message. As a general rule, a ship signals its position in latitude and longitude and when practicable, the true bearing and distance in nautical miles from a known geographical point may be given. An aircraft in flight should, if time permits include in its distress message the following information:

1. Estimated position and time of the estimate.
2. True heading and indicated airspeed.
3. Altitude.
4. Type of aircraft.
5. Nature of distress.
6. Intention of person in command (such as forced alighting on the sea or crash landing).

After transmission of its distress message, the mobile station transmits two dashes of approximately 10 seconds duration each, followed by its call sign, to permit direction-finding stations to determine its position.

The distress message must be repeated at intervals especially during "periods of silence," as follows: For 3 minutes, twice each hour, beginning at 15 and 45 minutes past the hour on 500 kHz and on the hour and at 30 minutes past the hour on 2182 kHz in certain designated regions. ("Periods of silence" are defined as periods of time during which all transmissions, except those of an emergency nature, are prohibited. All stations are required to maintain a listening watch on international distress frequencies during these periods.) The intervals used with other repetitions must be long enough to allow time for stations preparing to reply to operate their transmitters.

Immediately before a crash landing or a forced landing (on land or sea) of an aircraft, as well as before total abandonment of a ship or an aircraft, the radio apparatus should be set for continuous emission.

Distress Action

A mobile station which learns that another mobile station is in distress may transmit a distress message if the station in distress is not itself in position to transmit it or if the person in command of the ship, aircraft, or other vehicle, carrying the station which intervenes, believes that further help is necessary.

Mobile stations receiving a distress message which, beyond any possible doubt, is from a mobile station in their vicinity, must immediately acknowledge receipt (unless under radio silence). If the station in distress is not in their vicinity, they must allow a short interval of time before acknowledgement in order to permit stations nearer to acknowledge without interference.

Every mobile station that acknowledges receipt of the distress message and is in position to render assistance, must, on the order of the person in command, transmit the following information as soon as possible; its identification, its position, and the speed at which it is proceeding to the station in distress. Before sending this message, however, the station must insure that it will not interfere with the emissions of other stations better situated to render immediate assistance to the station in distress.

Any mobile station which is not in position to render assistance, and which has heard a distress message that has not been immediately acknowledged, must take all possible steps (unless under radio silence) to attract the attention of other mobile stations which are in a position to render assistance.

Distress Traffic

Distress traffic comprises all messages relative to the immediate assistance required by the mobile station in distress. In distress traffic, the distress signal must be sent before the call and at the beginning of the preamble of any message.

The control of distress traffic is the responsibility of the mobile station in distress, or the mobile station which has sent the distress call.

13615

These stations may, however, delegate the control of the distress traffic to another station.

The station in distress, or any mobile station near the distress station, may request silence from any or all stations which interfere with the distress traffic. It addresses these instructions to all stations or to a particular station only, depending on the circumstances.

When distress traffic has ceased or when silence is no longer necessary, a station which has controlled such traffic transmits on the distress frequency (and, if necessary, the frequency used for distress traffic) a message addressed to all stations indicating that the distress traffic has ceased.

URGENCY SIGNAL

The urgency signal indicates that the calling station has a very urgent message to transmit concerning the safety of a ship, aircraft, or other vessel, or of some person aboard or within sight. It has priority over all other communications, except distress. When the urgency signal is sent from a mobile station, it must, as a general rule, be addressed to a specific station and may be transmitted only on the authority of the person in command.

In radiotelegraphy, the urgency signal consists of three transmissions of the letter group XXX; in radiotelephony, it consists of three transmissions of the word PAN.

When an urgency signal is sent and followed by a message intended for all stations and calling for action by all stations, the station responsible for its transmission must cancel the signal as soon as it knows that the action is no longer necessary. This message of cancellation must be addressed to all stations.

SAFETY SIGNAL

The safety signal indicates that the station is about to transmit a message concerning safety of navigation or giving important meteorological warnings. The safety signal and the message which follows are sent on the distress frequency. With the exception of messages transmitted at fixed times, the safety signal, when used in the maritime mobile service, must be transmitted toward the end of the first available period of silence.

In radiotelegraphy, the safety signal consists of three transmissions of the letter group TTT; in radiotelephony, it consists of the word "SECURITE" (say-cur-i-tay) spoken three times.

The following type messages should be transmitted without delay and must be repeated at the end of the first period of silence:

1. Meteorological warnings.
2. Presence of tropical cyclones.
3. Presence of dangerous ice, wrecks, or other imminent danger to maritime navigation.

PRINCIPLES OF SINGLE SIDEBAND

Single sideband is not a new method of radio communication. It was first conceived in 1915, and has been in use since 1927. The decided advantages offered by SSB (single sideband) make it desirable to develop this method of communication with the possibility that it may eventually replace the DSB (double sideband) in present use.

Production of SSB units was delayed principally because of design obstacles affecting the high degree of stability required in both the transmitter and receiver units. Modern techniques of manufacture have perfected oscillators and filter circuits with sufficient stability and accuracy to make SSB feasible. In the relatively short period of time during which SSB has been in use in naval communications systems, it has produced highly satisfactory results.

The purpose of this discussion is to explain how SSB signals are generated, transmitted, and received, and also present the advantages of SSB over DSB.

To aid in understanding SSB, this discussion presents a review of amplitude modulation and shows a comparison between SSB and present day DSB operation. SSB is amplitude modulation with one sideband and the carrier removed. A more complete discussion of modulation is covered in Basic Electronics, NavPers 10087-B.

There are several methods of obtaining SSB or "semi-SSB" operation. Television, for example, employs a method of transmission whereby most, but not all, of one sideband is suppressed. In some installations the carrier is greatly, but not entirely suppressed. The greatly suppressed carrier is called a "pilot carrier." The pilot carrier is used in the receiver for reference and automatic control. True SSB has

13616

UNIT IV - ORTHOGRAPHIC PROJECTION

Practice in Visualization — Lesson 3

OBJECTIVE: To practice visualizing the shape of objects.

RELATED INFORMATION:

A draftsman is never adequately equipped without the ability to visualize the shape of objects. Before he can produce any working or orthographic drawing, he must be able to visualize. Every idea in the design or invention of a piece of machinery comes into the mind in pictorial form. When this can be clearly seen, he then knows he has, so to speak, come of age. Coupled with other facets of the trade, he then can seek more learned areas, once he has firmly grasped visualization and the proper placement of views.

ASSIGNMENT:

Place a $\frac{1}{2}$-inch border all around the 17 x 22 inch sheet issued to you and divide the sheet into the number of spaces shown in the drawing on the next page. Draw the views as shown, Problems 1 to 16, and add the missing line or lines which will complete the drawing. The objects all have plane, inclined, or curved surfaces.

1359

the carrier and one sideband entirely suppressed, with only the remaining sideband to be transmitted. Personnel requiring more detailed information on single sideband communications principles than that contained in this manual may refer to Fundamentals of Single Side Band, NavShips 93271.

AMPLITUDE MODULATION

Without modulation, the output of a transmitter is radio energy that has a frequency corresponding to the station's transmitting frequency. This is usually referred to as an unmodulated carrier. The unmodulated carrier is a continuous wave (CW) signal and occupies essentially no bandwidth in the frequency spectrum. Any single radiofrequency (RF) signal can be represented by an infinitely thin vertical line on a plot of amplitude versus frequency.

If a radio wave is to convey voice intelligence, some feature of the wave must be varied in accordance with the voice intelligence to be transmitted. Amplitude modulation consists of varying the amplitude of radiofrequency waves at an audio rate. Amplitude modulation may be defined as the variation of the strength of the RF output of a transmitter at an audiofrequency (AF). In other words, the RF energy has to increase and decrease in power, according to the audiofrequencies. If the audiofrequency is high, the radiofrequency must vary in amplitude more rapidly than if the audiofrequency is low. At the receiver, if the audio note is loud in volume, the radiofrequency energy must be increasing and decreasing by a larger percentage than if the audio note were soft. Thus, the RF variation introduced by the modulation process must correspond in every respect with the AF variations.

High Level

High level plate modulation is so named because the audio signal is injected in the plate circuit of the final RF power amplifier. The plate circuit of the triode class C power amplifier, V1 of figure 16-1, is tuned to a resonant frequency of 1 megahertz which is the transmitter carrier frequency. The plate current is 100 ma and the plate voltage supply is 1,000 v. The grid input driving voltage is produced by an RF oscillator and a buffer amplifier (used to isolate the oscillator from the power stage).

An audio signal of approximately 1,000 volts (peak) having a sine waveform and a frequency of 1,000 hertz is produced by the AF section and

AT.278

Figure 16-1.–High level modulation.

13617

appears as an output of the modulation transformer M. This audio output voltage is in series with the RF tank circuit, LC, and the plate power supply of B+ voltage Ebb.

Before an audio-modulation signal is introduced, the RF signal applied to the grid of V1 causes the triode to conduct periodically. During each conducting period, capacitor C charges. When the grid swings below cutoff, the triode stops conducting and the capacitor discharges through the coil.

The exchange of energy between the coil and capacitor accounts for the RF voltage developed across the tank. In this example, the voltage across the tank capacitor C which receives its charge from the 1,000-volt B+ supply is 1,000 volts neglecting losses.

Plate voltage varies above and below 1,000 volts as the capacitor varies between +1,000 and -1,000 volts. The value of the plate voltage is above that of the B+ supply during the part of the cycle when the grid voltage is below cutoff and the triode is not conducting. Plate voltage is below the B+ supply voltage during the time the grid is above cutoff and the triode is conducting. The output of the transmitter is an unmodulated carrier corresponding to the A portion of the output waveform shown in figure 16-1.

Now, assume that the AF (1 kHz) sinusoidal voltage is introduced at M in series with the RF tank and the B+ supply. The frequency of the RF voltage developed across the plate tank is 1,000 times the audiofrequency. Thus the time for one complete audio cycle is long enough to include 1,000 cycles of RF energy in the tank circuit, LC. Consider that portion of the AF cycle in which the voltage is gradually rising according to the sine wave variation so that the polarity aids the voltage of the B+ supply. For 250 cycles of radiofrequency (one-quarter of one AF cycle), the total voltage available for charging capacitor C in the plate tank circuit is increasing from 1,000 volts to a maximum of 2,000 volts. Assume that the capacitor charges to 2,000 volts. The plate voltage at the end of the 250 RF cycles is a maximum of 2,000 plus 2,000 or 4,000 volts. Thus with 100 percent modulation, the value of the peak-to-peak voltage across capacitor C has approximately double the peak-to-peak value it would have without modulation, or four times the B+ supply voltage as shown at point B.

The tank voltage starts to decrease between the 250th RF cycle and the 500th RF cycle, as the AF voltage falls from a maximum of 1,000 volts to zero volts during this period. From the 500th to the 750th RF cycle, the polarity of the AF voltage is reversed and reaches a maximum negative value at the 750th RF cycle, and the tank capacitor charges up to the difference voltage between the 1,000-volt B+ supply and the instantaneous AF value. At the instant the AF voltage is maximum negative (-1,000 volts at the 750th RF cycle), the tank capacitor is not charging at all, the tank voltage is zero, and the RF output energy is zero (point C). The AF voltage starts to rise from maximum negative to zero and the opposition that it offers to the plate supply voltage is reduced. The plate tank capacitor starts charging again, the RF tank current again gradually increases, and the output voltage increases.

The transmitting antenna is coupled to the tank, and the instantaneous antenna current increases and decreases in accordance with the tank current variation. The signal transmitted is 1 MHz modulated at 1 kHz.

Percentage of Modulation

The degree of modulation is expressed by the percentage of the peak-to-peak voltage of the audio to the plate B+ voltage. The effect of a modulated wave as measured by receiver response is proportional to the degree or percentage of modulation.

The percentage of variation of the total voltage of the final RF amplifier stage in high-level plate modulation depends upon the ratio of AF to unmodulated RF plate voltage. For example, if the plate voltage of the RF amplifier is 1,000 volts, and the AF voltage is 1,000 volts, the two voltages add (when they are acting in the same direction) to give 2,000 volts. They subtract (when they are acting in opposite directions) to give zero volts. The modulated plate voltage of the RF amplifier varies between zero and 2,000 volts at the audio rate. Since the variation is equal to the RF voltage variation of 2,000 volts (peak-to-peak) the transmitter signal is said to be modulated 100 percent.

It is important that the transmitted RF energy be kept as close to 100 percent modulation as possible because the output of a detector in a

13618

radio receiver varies with the amplitude of the AF component of the received signal. This is why a comparatively low-power station, well modulated, will often produce a stronger signal at a given point than a much higher powered but poorly modulated transmitter located at the same distance from the receiver. The useful limit for the percentage of modulation is 100 percent; this is obtained when the modulating voltage is equal to the plate supply voltage of the modulation amplifier. Under this condition the plate voltage of the amplifier is alternately zero and double the supply voltage (peak values). If the modulating voltage is greater than the supply voltage, over modulation can result; this condition is normally avoided since overmodulation causes severe distortion of the signal.

SIDEBANDS

The circuit of figure 16-1 may be regarded as being composed of two sources of signal voltage and a common load in series. One source is the RF generator, the other is the AF generator, and the load is the resonant tank circuit coupled to the antenna.

When two frequencies are introduced into a circuit having a common nonlinear load impedance (the class C amplifier), these two frequencies combine to produce two additional frequencies. These additional frequencies are called sidebands or sideband frequencies; they are the sum and difference of the original frequencies. However, this is not the complete picture. The nonlinear device will heterodyne or "beat" to produce a theoretically infinite number of frequencies in the output. These exist at the plate of V1 in figure 16-1.

The frequencies fall into four groups:

1. Frequencies identical with those introduced. The amplitude of the current of each frequency in this group is proportional to the amplitude of the voltage of the same frequency in the input wave.

2. Frequencies which are twice the frequency of each component in the input wave—(second harmonics). Harmonics other than the second are produced, but they are very weak and easily dispensed with.

3. Frequencies which are equal to the sum of each frequency in the input with every other frequency in the input; in this case, carrier frequency plus modulating frequency, or upper sideband frequency.

4. Frequencies which are equal to the difference of each frequency in the input from every other frequency in the input; in this case, carrier frequency minus modulating frequency, or lower sideband frequency.

In this example of the principle of modulation, the two frequencies, 1,000,000 hertz (RF) and 1,000 hertz (audio) are impressed on the nonlinear impedance. The following distortion frequencies will also exist: 2,000,000 hertz, 999,000 hertz, 1,001,000 hertz, and 2,000 hertz.

When the carrier plus its upper and lower sidebands are transmitted through a tank circuit resonant at the carrier frequency, each component of a pair of sideband frequencies is shifted in phase. One is advanced and the other retarded by equal amounts as shown in figure 16-2. The curves show how the carrier and sidebands combine algebraically to produce an amplitude-modulated wave with 100 percent modulation by a steady tone.

Figure 16-3 illustrates that the only frequencies (contained in the total output) that fall within the range of the resonance curve are the 1000 kHz, the 999 kHz, and the 1001 kHz. The transmitter final amplifier plate resonant circuit is tuned to the carrier frequency and it attenuates all frequencies present at the plate except the carrier and its upper and lower sideband.

AT.279

Figure 16-2.–Modulation waveforms.

13619

AT.280

Figure 16-3.—Selectivity curve.

In actual practice (for communication uses) the modulating wave is usually a complex wave instead of a simple sinusoidal one. In the case of speech or music, the modulating wave may be a wide band of frequencies. For example, if the modulating wave should include frequencies throughout the range of 100 hertz to 5,000 hertz and the carrier is still 1000 kHz (1,000,000 hertz), then two sidebands would be produced. The upper sideband would be from 1,000,100 hertz to 1,005,000 hertz, and the lower one would be in the range of 995,000 hertz to 999,900 hertz. For each component of the original complex audio input band there is a corresponding component in both the upper and lower sidebands.

Since the purpose of this discussion is to emphasize the sideband characteristics of RF waves, as related to communication, it is convenient to use a sideband label for amplitude modulation. This type of modulation can be called double sideband (DSB), to distinguish it from SSB. Double sideband is a better term because, instead of transmitting only one frequency, the antenna is actually radiating two sidebands plus the carrier frequency. These frequencies are close together and within the bandwidth of the RF amplifier resonant circuit.

Double Sideband Power Requirements

The amount of power required to modulate a DSB transmitter depends on the percentage and type of modulation. To modulate a carrier 100 percent with a pure sine wave of audiofrequency requires an audio power source equal to one-half the RF carrier power. With 100 percent modulation, the amplitude of each sideband is one-half the amplitude of the carrier. Power is proportional to the square of the current; thus each sideband contains one-half the current and one-fourth the power. This is shown in figure 16-4 which depicts the carrier and the sideband waveforms which are the resultant of modulating a 1000 kHz carrier with a 1 kHz tone, assuming 100 percent modulation.

As shown in figure 16-4 if power output is to remain constant, it would be necessary to increase the input power by 50 percent when shifting from unmodulated to tone modulated operation, assuming 100 percent modulation. In voice modulation the greatest portion of the AF components will not modulate the carrier 100 percent. Thus, the power requirements are considerably less than that required for tone modulation.

An amplifier in a modulation circuit must handle extremely high peak currents; up to four times the power it dissipates during the periods when no modulation is applied.

Demodulation

New frequencies are created in the process of demodulation. For example, if a 1 kHz signal modulates a 1000 kHz carrier, sidebands of 1001 kHz and 999 kHz are created as shown in figure 16-4. Also, if the 1000 kHz signal were made to modulate the 1001 kHz sideband, an upper frequency of 2001 kHz and a lower frequency of 1 kHz would be created. Provided that propagation does not cause any shift in their phases relative to each other, the 1 kHz signals are in phase. Note that 1 kHz is the original modulating frequency. This is the mechanism of the demodulation action. A carrier frequency and received sideband frequencies modulate one another and produce new frequencies, among which is the desired audiofrequency.

Sum and difference frequencies are important in the modulation and demodulation of DSB waves. To produce sum and difference frequencies, it is necessary to change the shape of the input waves. This is done by impressing the waves on a nonlinear device. DSB modulators and demodulators are usually nonlinear devices, such as class C amplifiers and diodes.

1C43620

AT.281

Figure 16-4.—Carrier and sideband power.

It has been pointed out that in DSB systems there exists two sidebands that are demodulated in the receiver to produce a single audio signal that carries the voice intelligence heard in a speaker or headset. In the process of demodulation a signal equal to the original audio signal is produced from two sources; one by each sideband beating with a signal of the same frequency as the carrier frequency. Since either sideband contains all the intelligence, one sideband may be removed by a filter without interfering with the overall transmission of the original audio signal. The total RF transmission band covered would be cut in half if one sideband were eliminated, with the result that more channels could be operated within a given range of frequencies. In addition, distortion caused by propagation effects would be eliminated.

The only purpose of the carrier is to serve in the demodulation of the incoming signal. Since the carrier is used in the demodulation process, it is possible to eliminate the carrier at the transmitter and reintroduce it at the receiver. This carrier elimination is the major principle of SSB operation, and is discussed in subsequent paragraphs.

CARRIER AND SIDEBAND SUPPRESSION

The carrier may be eliminated or suppressed by some arrangement such as the balanced-modulator circuit shown in figure 16-5.

The carrier voltage is applied to the two modulator tubes in the same phase (push-push) while the modulator signal voltage is applied in opposite phase (push-pull) to the two grids by means of the center-tapped transformer. The outputs in the plate circuits of the two tubes are combined through a transformer with a center-tapped primary in such a way that voltages applied to the two grids in push-push cancel each other in the output (plate circuit); whereas voltages applied to the two grids 180° out of phase (push-pull) are added in the output. Thus the carrier voltage, which is applied to the two tubes

13621

AT.282

Figure 16-5.–Balanced modulator.

in push-push, does not appear in the secondary of the output transformer. On the other hand, the sideband components (audio), which are applied in push-pull, are added in the output. The result is an output that is a modulated wave from which the carrier component has been removed.

The output from the balanced modulator tubes contains three of the four groups of frequencies already mentioned in the discussion of nonlinear devices. These groups are as follows:

1. Frequencies identical with the components of the signal voltage in the input, but none at the frequency of the carrier.

2. Frequencies equal to the sum of the carrier frequency and each component in the signal.

3. Frequencies equal to the difference between the carrier frequency and each component in the signal.

Now that the carrier has been eliminated, all that remains is to eliminate one of the sidebands. This can be accomplished by either the filter method or the phasing method. These methods are explained following a discussion of the various types of filters.

Both SSB transmitters and SSB receivers require extremely selective bandpass filters in the region of 100 kHz to 500.

In receivers, a high order of adjacent channel rejection is required if channels are to be closely spaced for conservation of spectrum space. In SSB transmitters, the signal bandwidth must be limited sharply in order to pass the desired sideband and reject the other sideband. The filter used, therefore, must have very steep skirt characteristic (fast cutoff) and a flat bandpass characteristic in order to pass all frequencies in the band equally well. These filter requirements are met by crystal filters, LC filters, and mechanical filters.

Suppression Devices

CRYSTAL FILTERS.–Until recently, crystal filters used in commercial SSB equipments were in the 100 kHz range. Such filters have excellent selectivity and stability characteristics, but their large size makes them subject to shock or vibration deterioration. Also, their cost is quite high.

Crystal filters with extended frequency range, and smaller in size, are being developed. These filters are more acceptable for use in SSB equipment.

LC FILTERS.–LC filters have been used at IF frequencies in the region of 20 kHz. However, generation of the SSB signal in this low frequency range requires an additional mixing stage to obtain a transmitting frequency in the high-frequency range. For this reason, LC filters are not widely used in SSB equipment.

MECHANICAL FILTERS.–Recent advancements in the development of mechanical filters have led to their acceptance in SSB equipment.

13622

Mechanical filters have excellent rejection characteristics, are extremely rugged, and are small enough to be compatible with miniaturization of equipment. Another advantage of the mechanical filter is a Q in the order of 10,000, which is about 100 times the Q obtainable with electrical elements.

Although the commercial use of mechanical filters is relatively new, their basic principles are well established.

The mechanical filter is a mechanically resonant device that receives electrical energy, converts it into mechanical vibration, then converts the mechanical energy back into electrical energy at the output. The mechanical filter consists basically of four elements:

1. An input transducer that converts the electrical input into mechanical oscillations.
2. Metal disks that are manufactured to be mechanically resonant at a certain frequency.
3. Coupling rods that couple the metal disks.
4. An output transducer that converts the mechanical oscillations back into electrical oscillations.

Figure 16-6 shows the elements of the mechanical filter.

The transducer may be either a magnetostrictive device or an electrostrictive device.

The magnetostrictive transducer utilizes the principle that certain materials can be made to elongate or shorten when in the presence of a magnetic field. Therefore, if an electrical signal is sent through a coil whose core is made of a magnetostrictive material, the electrical oscillation will be converted into mechanical oscillation. The mechanical oscillation can then be used to drive the mechanical elements of the filter, which are the disks.

The electrostrictive transducer utilizes the principle that certain materials, such as piezoelectric crystals, will compress when subjected to an electric current or voltage.

Both types of transducers have a natural resonant frequency. They are manufactured to be resonant at a specific frequency. Transducers are chosen for a particular application, such as the ability to pass the frequencies of one sideband and reject all other frequencies.

Figure 16-7 (A) is the block diagram of an SSB transmitter that utilizes mechanical filters. Filtering action by the mechanical filter (similar to that shown in fig. 16-6) is accomplished in the following manner. The first bandpass filter will receive only the two sidebands of the modulated signal from the low-frequency modulator. (Elimination of the carrier by the balanced modulator was explained earlier.)

The metal disks of the mechanical filter pass only the frequencies of the desired sideband. Although the transducer driving rod applies the frequencies of both sidebands to the

AT.283

Figure 16-6.—Mechanical filter.

the terminal end of the filter. It is interesting to note that either end of the filter may be used as the input, and either end used as the output.

By varying the mechanical coupling between the disks (that is, by making the coupling rods larger or smaller) the bandwidth of the filter is varied. Because the bandwidth varies approximately as the total area of the coupling rods (in magnetostrictive transducers), the bandwidth can be increased by using either larger coupling rods or more coupling rods. Mechanical filters with bandwidths as narrow as 0.5 kHz and as wide as 35 kHz are practical in the 100 kHz to 500 range.

Suppression Methods

The most simple and direct means of accomplishing SSB transmission by the filter method would be to filter out the carrier and one sideband of the conventional DSB system. This is not feasible since, if this system were used with conventional DSB transmitter circuits, filters capable of dissipating large amounts of power would be required in the transmitter output stage. This would result in a waste of power. To avoid this, the balanced modulators and filters are used in the low-power stages of a transmitter. The filter is required to accomplish the following:

1. Pass the desired sideband.
2. Limit the bandwidth of the desired sideband to that required for an intelligible communications circuit.
3. Provide adequate suppression of the undesired sideband.
4. Provide some attenuation of any remaining carrier frequency.

The ideal filter characteristics are shown as a solid line in figure 16-8. The solid line represents the ideal filter curve, which would pass only the upper sideband and reject the carrier and the lower sideband. The dotted line represents the filter curve that usually exists, which may vary depending on the type of filter used. A filter having those characteristics would be used as the first filter in figure 16-7 (A). In actual practice such a filter does not exist. But there are some filters that approach the requirements stated above, such as the electromechanical bandpass filter and the crystal lattice filter.

AT.285

Figure 16-8.–Filter characteristics.

Refer again to the block diagram in figure 16-7 (A) which is a block diagram showing the use of mechanical filters and a balanced modulator. The frequencies used in the illustration are the result of using a 2,000 hertz single-tone audio signal. In actual practice a complex audio signal would normally be utilized.

The 2 kHz audio signal is amplified and mixed in the balanced modulator with a 100 kHz carrier. Remember, the carrier does not appear in the output of the balanced modulator. When mixed, however, the sum and difference frequencies do appear in the output. The 2 kHz (fundamental) signal is so far from the frequency of the mechanical filter that it can be ignored. The dotted line shows where the carrier has been removed. Removal of the lower sideband is accomplished by the mechanical filter.

Because the remaining sideband is too low in frequency, it must be mixed again with a 3 MHz signal to raise it to the desired transmitter frequency. Again, the balanced modulator removes the two fundamentals and applies the two new sidebands (sum and difference) to the linear power amplifier. The input and output circuits of the linear power amplifier are tuned to reject one sideband and pass the other to the antenna for transmission.

In actual practice a high frequency oscillator, shown in dotted lines in figure 16-7 (A), would be used prior to the power stage. Also, the medium frequency oscillator is variable so that transmitter output frequency can be varied.

The power stage may be two or three power amplifiers. Since the carrier is suppressed in the balanced modulators and one sideband is removed by the filters, all of the transmitted energy is in the single sideband. This is sometimes called "talk power." Since only the talk power is radiated, it follows that when no audio is being applied to the transmitter there is no transmitter output, even though the transmitter is fully activated.

Since only one sideband is required for signal transmission, single sideband transmitters may be used to transmit two messages, one by the lower sideband and the other by the upper sideband. In order to do this, each message modulates the same carrier but in different modulators, as illustrated in figure 16-9. In a transmitter of this type, the outputs of the two modulators usually contain the same carrier (reduced) as well as the different sidebands.

Filter circuits are provided for removing the upper sideband from one modulator output and the lower sideband from the other. The remaining sideband frequencies are then radiated from one antenna along with the reduced or suppressed carrier. Thus, each of the two sidebands conveys a separate message and may be used to provide a separate audio channel. Reception of the two channels requires only one receiver with suitable circuits for separating and demodulating each channel.

Phase cancellation can also be used to eliminate the unwanted sideband. One system uses two balanced modulators connected as shown in figure 16-7 (B). Balanced modulator No. 1 has the carrier and modulating signals directly applied, while in balanced modulator No. 2 both signals are shifted 90° in phase. When the outputs of these two modulators (Nos. 1 and 2) are added, one phase is eliminated or canceled, and the other is reinforced.

SSB AMPLIFICATION

The most desirable combination of characteristics in linear amplifiers combines low distortion with maximum power gain. A linear amplifier is an amplifier having a certain power or voltage gain and an output waveform which exactly resembles the input waveform. Speech amplifiers or modulators are linear

AT.286

Figure 16-9.–Two-channel SSB system.

13626

1360

amplifiers. The speech amplifiers are linear audio voltage amplifiers while the modulators are linear audio power amplifiers. The only difference between linear audio amplifiers, and SSB amplifiers is the frequency involved—one is audiofrequency and the other radiofrequency. The same operating conditions are used, such as plate voltage, bias, load impedance, and so forth, in both cases. As has already been mentioned, nonlinearity produces distortion and distortion is highly objectionable in SSB because it can produce splattering into adjacent channels. This splattering is easily detected by sensitive receivers.

Class A operation of amplifiers gives a high degree of linearity and they are usually the ones referred to when speaking of linear amplification. But these have low power gain, and thus would result in a considerable power loss in high-power transmitters. Class AB operation is used in amplifiers when higher power gain is needed. High gain is required in SSB amplifiers because the modulated signal is usually generated at low levels (1 watt or less). To raise this level to a kilowatt requires high gain. To obtain high gain with a minimum number of stages and circuits requires the use of high gain tetrodes or pentodes, usually operated class AB. A minimum number of amplification stages is desired because each amplification stage produces distortion. However, negative feedback in RF circuits can be utilized to reduce distortion in the same manner as negative feedback in audio circuits. This is done by applying a sample of the output waveform to the amplifier's input to correct any distortion produced within the amplifier.

SSB RECEPTION

In the reception of SSB, the receiver must have rigid frequency stability because the reception is not as simple as with DSB signals. As previously mentioned, the receiver has the problem of furnishing an artificial carrier, since the SSB signal does not contain a carrier against which the sideband signals can be heterodyned in the receiver to demodulate the sideband and produce useful audio signals. As a rule, the artificial carrier is furnished by a highly stable beat frequency oscillator in the receiver.

It is necessary that the SSB transmitter have the same degree of stability as the receiver. The maximum allowable drift between transmitter frequency and receiver frequency is about 50 hertz for good voice reception. A 50 hertz difference between transmitter and receiver will distort or change the pitch of the person's voice by 50 hertz. Although the intelligence is still there, it does not constitute "good voice reception."

Figure 16-10 is a block diagram showing the essential functions of an SSB receiver.

The receiver employs necessary switch and tuning circuits to receive any signal within its frequency range, and to switch from upper sideband to lower sideband reception.

After the received signal is amplified, it is applied to mixer stages that lower the frequency. This is done in the same manner by which the frequency was raised in the transmitter. The carrier, necessary for heterodyning in the detector, is then inserted. Notice that the carrier generator is controlled by a frequency standard, as is the stabilized master oscillator (SMO), to maintain rigid frequency stability. After detection the original 2 kHz signal is fed to conventional audio amplifier stages.

Many of the units of an SSB receiver are identical with units of the SSB transmitter. The frequency standard, carrier generator, and SMO are identical. The double conversion mixer and amplifier unit of the receiver can be made identical to the double conversion mixer and amplifier unit of the transmitter. Because of this similarity, transceivers can be constructed with much of the circuitry used for both transmitting and receiving. This can be accomplished by merely adding switching arrangements to reverse the direction of signal flow.

SSB ADVANTAGES

In conventional DSB techniques of communication, there is a carrier, an upper sideband, and a lower sideband. The sidebands "beat" with the carrier to produce a single audio signal that carries the voice intelligence that is heard in the speaker or headset. If the upper or lower sideband is shifted in phase due to

13627

AT.287

Figure 16-10.—SSB receiving system.

multipath skywave propagation conditions, the signal heard is fuzzy, distorted, and in all probability quite loud. It is not uncommon to receive a report stating "loud but distorted." One sideband may experience a slight phase shift, thereby nearly canceling the other. The distortion produced causes the loss of intelligibility. Fading or slight phase shift of the carrier can also produce similar results. These problems reportedly do not exist in the suppressed-carrier type of SSB, particularly in the frequency range below 14 MHz.

In conventional DSB technique of communication, with 100 percent modulation, approximately (neglecting losses) two-thirds of the transmitter's radiated power is in the carrier, and the remaining one-third is divided equally between the two sidebands. DSB and SSB modulation relationship is illustrated in figure 16-11. An unmodulated carrier of frequency f1 with an average of 1,000 watts is shown in (A) of the figure. Information can be transmitted by keying the carrier on and off, as in CW. The entire 1,000 watts of carrier power is used in transmitting information. In figure 16-11 (B) the same transmitter is shown being modulated 100 percent by a single sinewave tone of frequency f2. The useful information is contained only in the upper sideband frequency (f1 + f2) and lower sideband frequency (f1 - f2) that exist on either side of the carrier frequency.

Notice that the useful power is only 50 percent of that attained by the CW in figure 16-11 (A). For practical voice modulation waveforms, this useful power may not exceed 30 percent of the total power. Figure 16-11 (C) represents a method of transmission known as a twin-channel single-sideband reduced-carrier system. (See fig. 16-9.) The carrier is not completely suppressed, but is reduced approximately 20 db in amplitude, serving as a pilot

13628

AT.288

Figure 16-11.–DSB and SSB modulation power relationship.

carrier. This pilot carrier is used as a reference for obtaining a reinserted carrier of correct frequency and phase in the receiver demodulator circuits, and for the AGC (automatic gain control) circuits. Figure 16-11 (D) represents a single-sideband suppressed-carrier system with complete suppression of the lower sideband and carrier. The only energy radiated by this method is modulation energy.

In this method a higher degree of oscillator frequency stability is required for both the transmitter and receiver circuits than for the method using the pilot carrier. Thus, with the suppressed-carrier SSB system, all of the power goes into the single sideband which carries the useful voice intelligence.

Since there are good and poor suppressed-carrier SSB signals as well as good and bad DSB signals, it would not be fair to compare a good DSB signal with a bad suppressed-carrier SSB signal, or vice versa.

In any system of comparison, it is essential that conditions under which the comparison is made be clearly defined. Figure 16-12 illustrates one method of comparison of suppressed-carrier SSB and DSB. The comparisons made here assume coherent detection of sidebands in DSB and also ignore the possible differences that can occur under various propagation and interference conditions. Figure 16-12 compares "talking power" between DSB and SSB. It illustrates that as bandwidth is decreased SSB transmitter requires progressively less power output to obtain the same "talk power" as a DSB transmitter. In this illustration the output of the DSB transmitter is 1,000 watts.

Figure 16-12 (A) illustrates that a 1,000-watt DSB transmitter will "talk" just as loud as a 1,000-watt SSB transmitter if both are received on a wide-band (6 kHz) receiver. Figure 16-12 (B) illustrates that under optimum conditions–that is, DSB received at bandwidth of 6 kHz and SSB received at bandwidth of 3 kHz–the talking power of a 500-watt suppressed carrier SSB transmitter is equal to that of a 1,000-watt DSB transmitter. Figure 16-12 (C) illustrates that if both DSB and suppressed-carrier SSB are received on a narrow bandwidth receiver, then the talking power of the 250-watt SSB transmitter is equal to that of a 1,000-watt DSB transmitter.

It has generally been accepted that, under normal operating conditions with moderate signal-to-noise ratios, the improvement in gain using SSB is between 6 and 9 db over the gain of an equivalent DSB transmitter. The suppressed-carrier SSB transmitter provides 6 db gain and the remaining db gain is derived from

13629

Figure 16-12.–DSB and SSB power comparison.

the narrow-band single-sideband receiver's selectivity. Propagation conditions determine the relative advantages of suppressed-carrier SSB over DSB. As the interference and/or selective fading becomes worse, SSB indicates a greater advantage over DSB.

Another advantage of SSB operation is that interference is reduced. In normal voice DSB communication, the carrier of the transmitter remains on the air until the transmitter is turned off. If a second transmitter transmits while the carrier of the first station is on the air, distortion results. Squeals and howls are caused by the heterodyning of two or more signals being transmitted at the same time. With SSB, as soon as the sender stops speaking into the microphone, "talk power" in the sideband leaves the air even if the transmitter is still on; receiving equipment is not affected by the SSB carrier (reduced carrier when used) alone.

When two SSB stations transmit at the same time, a receiving station can receive through the interfering station in the same way that an individual is able to listen to more than one conversation at the same time.

INTEGRATED COM-NAV-IFF SYSTEMS

The integrated communications, navigation, and identification system was brought about by the advent of the weapons system concept in naval aircraft. This system, called COM-NAV-IFF (CNI) in some installations and INTEGRATED ELECTRONIC CENTRALS (IEC) in others, is the natural result of the expanded electronic functions, restricted space, critical weight factors, and more severe environmental conditions imposed upon the newer high performance naval aircraft.

BASIC CONCEPTS

The integrated units for specific aircraft are designed to best fit into the overall weapon system of the aircraft. The system is designed to combine into one integrated system the functions previously performed by numerous independent electronic equipments. Figure 16-13 is a block diagram of a typical CNI system. Functional names of components are used; rather than AN nomenclature, since this diagram is representative of a general system rather than a specific aircraft configuration.

In most CNI systems the mounting racks serve a dual purpose. They act as shock mounts and in addition serve as a specialized chamber for distributing cooling air to each of the major components. In addition, components which contain high voltage circuits are pressurized to prevent arc-over at high altitude. The units

13630

AT.290

Figure 16-13.–Typical CNI system.

which do not require pressurization are supplied directly with cooling air.

Communications Function

UHF radio communication facilities are provided by one or more transceiver units, permitting voice transmission and reception on any of 1750 channels in the frequency range of 225.0 MHz to 399.9 MHz. A separate fixed frequency guard channel receiver in the transceiver unit is normally tuned to the emergency frequency of 243.0 MHz. An auxiliary UHF receiver is also normally included in the system. This receiver operates on any one of 20 preset channels in the frequency range of 265.0 MHz to 284.9 MHz, and on an additional guard channel. The auxiliary receiver is employed with the UHF ADF system in order to provide independent UHF direction-finding functions without disrupting the normal communications facilities.

Navigation Function

The navigation function includes both TACAN and ADF. The TACAN facilities are provided by two units, a radio receiver-transmitter and a pulse decoder. The output of the pulse decoder is used to drive indicators which display bearing and distance to the selected TACAN beacon, deviation from a selected course, and TO-FROM information to indicate whether the selected course is to or from the beacon.

The UHF ADF can be operated using two receiver sources, the UHF communications receiver or the auxiliary receiver.

Indentification Function

The identification facilities are provided by a pulse type transponder which automatically radiates replies to interrogations from ground, shipboard, or airborne IFF stations. Either normal (Mark X IFF) or selective indentification feature (SIF) coding of the replies may be utilized. This facility performs the functions provided by both the AN/APX-6B and the AN/APA-89 in older aircraft.

Power Supplies

Power supply modules distribute power from a centralized source to the major units. Special emergency switching features remove power from certain navigation functions to reduce the load on the power source in case of flame out, generator failure, or other emergency. The specific functions which are not available in an emergency will vary from one aircraft to another; information on this subject may be found in the technical manuals for specific aircraft models.

The centralized power supply provides a means of saving weight in an integrated installation. The components utilized in power supplies are often very heavy when compared to other electronic components, therefore, combining the power supplies eliminates numerous heavy components.

F-4B CNI SYSTEM

The CNI system for the F-4B aircraft is the Integrated Electronic Central AN/ASQ-19. It provides UHF communications, TACAN and ADF navigation, radar identification (IFF), instrumentation, and interphone functions. It is packaged in five major units: UHF Communications, unit 1; Navigational RF, unit 2; Navigational Instrumentation, unit 3; IFF/Coder, unit 4; and Auxiliary Receiver/ADF/Power Supply, unit 5. Placement of these units as well as some minor units and associated components is depicted in figure 16-14.

Units 2 through 5 are mounted above and below a common shelf installed aft of the aircraft's nosewheel well. The shelf as a whole is shock-mounted; it provides interunit wiring and connections, and serves as a plenum chamber for refrigerated air. Of these four units, the Navigation RF Unit is the only one in a pressurized case.

UHF Communication Unit

The UHF communication unit (fig. 16-14, unit 1), is located in the aft cockpit; it, too, is pressurized, but has a self-contained blower circulating cockpit air through a heat exchanger. Accessories to the system include fore and aft integrated control boxes, unit 6; fore and aft station intercommunication system, units 7 and 8; ADF antenna, unit 9; and bearing-distance-heading indicator, unit 10.

In general, the modules, though improved for the CNI system, were utilized in previously developed Navy modularized equipment. Radio receiver-transmitter, unit 1, is designed to provide AM radiotelephone communication in the frequency range 225.0 MHz to 399.9 MHz. It operates on any one of 1750 frequency channels with 100 kilohertz spacing at 20 watts power output. A guard channel is provided by a separate guard receiver module incorporated as part of the circuitry of unit 1.

TACAN Units

The TACAN subsystem, units 2 and 3, uses pulsed radio signals from 962 MHz to 1213 MHz to measure aircraft distance and bearing to a TACAN surface station. There are 126 preset channels available to the operator.

Distance-measuring pulses originating in the airborne transmitter are transmitted to the ground radio station which acts as a transponder. Distance of aircraft to station is determined by measuring the elapsed time between the transmission of a challenging or interrogation pulse signal from the airborne transmitter, and the receipt of a corresponding reply pulse from the radio beacon.

Reference bursts and amplitude modulation intelligence are produced in the radio station to provide bearing and identification information for the aircraft. The radio station antenna pattern rotates at 900 rpm and produces a varying field intensity at the receiving antenna. This varying signal intensity produces the 15 Hz and 135 Hz amplitude modulation of the signal received by the airborne receiver. The reference bursts bear a constant relationship to the maximums and minimums of the rotating antenna pattern, and the consequent phase relationship of the AM and the reference bursts received by units 2 and 3 are used to determine the bearing of the aircraft with respect to the radio station.

13632

AT.291

Figure 16-14.–Integrated Electronic Central AN/ASQ-19.

13633

IFF Coder Unit

The IFF-Coder, unit 4, is a pulse type transponder using a single omnidirectional receiving and transmitting antenna. The equipment normally receives on 1030 MHz and transmits on 1090 MHz. An IFF control box (Radar Set control C-1159/APX-6B) is used to turn on the equipment and to select some of the modes of operation. The various Selective Identification Feature (SIF) reply codes for two of the three challenging signals are set up on an SIF control box (Radar Set Control C-1272A/APA-89). The third SIF code (mode 2) is set up directly on unit 4. Selection of Mark X or SIF replies is made by a switch on unit 4, and cannot be changed during flight.

The airborne antenna receives a challenging signal from interrogator equipment. This consists of pairs of pulses, with a definite time interval between the two pulses of each pair. The receiver detects and amplifies the signal and delivers it to the decoder circuits. If accepted by the decoder circuit in the equipment, the Mark X signal will go directly to the transmitter, and a reply signal is transmitted to the interrogator equipment, where the signal is then displayed on a radar indicator.

If the IFF-Coder is interrogated by an SIF challenge, the decoder output signal goes to a coding circuit in which a reply pulse train is generated. The pulse train is delivered to the transmitter. Upon being received at the interrogator, the pulse train is decoded, and the decoded signal is displayed on the the radar indicator.

Auxiliary Receiver/ADF/Power Supply Unit

The system central power supply portion of unit 5, provides the B + voltages of less than 500 volts necessary for operating all units of the system. The input a-c and d-c power is supplied from two separate sets of aircraft power buses designated main and essential. When an aircraft emergency arises, power is removed from the main buses and the emergency relays are energized automatically, placing the CNI system in emergency operation. The units operating after this emergency switching takes place are the UHF Communications Unit, at reduced power, and the radar identification (IFF) equipment. The ADF and TACAN functions are inoperative since the auxiliary receiver and TACAN B + voltage is removed.

For checking the system on the ground, external power is applied to the main aircraft buses through the ground power connector. A CNI ground power switch located in the left main wheel well is provided and must be manually thrown to energize the equipment. This switch is an electrically held type that must be reset if the ground external power is interrupted. Aircraft power bypasses this switch when the engines are operating; and during flight, the system cannot be deenergized.

The remaining portions of unit 5 are the ADF and the auxiliary receiver. The ADF subsystem uses either the auxiliary receiver in unit 5 or the main receiver, unit 1, in conjunction with the ADF antenna, unit 9, to determine the bearing to a received station. The antenna element has a cardioid pattern which is switched 180° at a 100 Hz rate. The switching action produces modulation on the RF signal (which is detected in the receiver and supplied as an error signal to a servoamplifier). The servosystem positions the antenna element until it is alined with the wave front of the received signal. The antenna maintains this relationship with respect to the signal throughout normal flight maneuvers of the aircraft. The position of the antenna element, relative to the aircraft, is transmitted to the Bearing-Distance-Heading Indicator (BDHI), unit 10, and displayed on the No. 1 pointer. ADF information is also supplied to the Horizontal Situation Indicator (HSI), a part of the instrument system.

The auxiliary receiver in unit 5 is normally used for ADF, and it provides 20 preset channels over the 265.0 MHz to 284.9 MHz range, plus one guard frequency channel at a fixed 243 MHz.

Integrated Control Unit

The communication and navigation functions of the AN/ASQ-19 are controlled by the integrated control, unit 6, selected by the "take command" relays. Two take command pushbotton switches are located on the lower position of each unit 6. One, labeled COM CMD, determines who has control of unit 1. The other, labeled NAV CMD, determines who has

control of TACAN. The frequency control for the communication system, the auxiliary receiver, and TACAN are independent of each other. The TACAN function selector also is independent. The function selector switch provides selection of the UHF communication and auxiliary receiver functions.

Intercommunication Units

The intercommunication units, units 7 and 8, of the AN/ASQ-19 provide intercockpit communication in the F-4B aircraft. Unit 7 is the intercom station in the pilot's cockpit; unit 8 is the intercom station in the radar observer's cockpit. An external intercom connection is incorporated into the system for ground personnel. The intercom stations receive and amplify signals from units 1, 2, 3, and the auxiliary receiver of unit 5. In addition, the microphone output in either cockpit is connected to the transmitter of unit 1 by operating the push-to-talk button, thus allowing either pilot or radar operator to communicate. Two transistorized, encapsulated amplifiers are used in units 7 and 8 to amplify the AF output from the microphone and the external audio inputs. Emergency switching facilities allow any one amplifier to be bypassed in the event of their failure. This permits intercockpit communication to be maintained if one amplifier goes dead in each unit.

Antenna System

The antenna system of the F-4B has a pair of antennas, upper and lower, used for both the IFF and TACAN at L band frequencies with two independent automatic antenna switches. The antennas are standard annular slot antennas. A modified blade antenna is mounted in the fin cap and used for the upper communications antenna. A low drag blade is used for the lower antenna. The pilot has the option of selecting either antenna by an antenna selector switch located on the left console of the forward cockpit. The ADF antenna, unit 9 is located on the underside, aft of the radome. This antenna works in conjunction with either the auxiliary receiver or the UHF communication system, whichever is selected for the ADF function on the integrated control box.

Construction

In the CNI system aboard the F-4B aircraft, the modular construction concept has been applied. Circuits have been broken down into functional subdivisions and packaged independently as plug-in modules adhering to a standard size factor. A major functional unit consists of a group of these modules mounted on a chassis in a case which provides interconnecting wiring, radio interference filtering, and cooling distribution.

The modular approach has given a high degree of flexibility in view of the mission and space considerations of this aircraft. It has also reduced costs and accelerated the engineering production cycle, helping to put the full weapon system into the air faster.

Cooling System

Improved thermal design is another important feature of the CNI system. Basically, the problem is to maintain the surface temperature of each component in the system at a value which will insure a high degree of component reliability. This must be done with a cooling system having the smallest possible size and weight.

Neither natural convection and radiation nor the use of integral blowers are acceptable means of cooling if high ambient temperatures (due to local heat dissipation or high aircraft skin temperatures) exist in an equipment rack. The problem is aggravated at extreme altitudes where mass flow from integral blowers drops to negligible values. A forced-air cooling system using an outside source of cooling air is required to hold the component temperatures within acceptable limits.

Since the cooling system must be held to a minimum size and weight, the CNI system is designed to minimize the power dissipation required. Careful circuit design keeps the dissipation in each module as low as practicable. The elimination of individual blowers with their inherent heat dissipation, and the use of a central power supply further reduce the overall heat produced in the system. High temperature components are used as extensively as possible to reduce the amount of cooling air required. Finally, and perhaps most im-

13634

portant, the flow of cooling air through each module is carefully controlled to give a high degree of cooling efficiency and still prevent overcooling of any module. In this manner, the required capacity of the cooling system is kept at a minimum, and the reliability and total life of the equipment are extended to a maximum.

COMMUNICATIONS RECEIVERS AND TRANSMITTERS

One of the duties of a technician may be to operate and maintain many different types of aircraft communication equipments. These equipments differ in many respects; however, in other respects they are similar. It is beyond the scope of this training manual to present information that relates to all of the many different equipments; therefore, only representative sets are discussed.

Distinctive features of naval airborne communications equipment include automatic tuning, subassembly and modular types of construction, shock mounting of major units, and pressurization, as well as the electronic components and circuitry employed.

Automatic tuning, which makes possible rapid selection of preset channels, is used in most modern naval airborne communication systems. This feature is essential because channel changes must be made accurately and quickly. Since the automatic system provides great simplicity of control, the entire operation is usually accomplished by means of a single dial.

The use of shock mounting is required because of vibration and the extreme physical forces present in normal operation in aircraft. The construction of electronic equipment in subassemblies and modules simplifies maintenance and repair. It permits the removal and replacement of sections containing defective or malfunctioning parts without dismantling the entire equipment.

All radio communication equipments, whether military or civilian, are designed for operation within certain well-defined frequency limits. In this chapter the terms used in reference to frequency bands designate major portions of the radio spectrum as discussed in chapter 9 of this manual. The designations and abbreviations are those in general use.

GENERAL PURPOSE RECEIVER AN/ARR-41

Radio Receiving Set AN/ARR-41, consisting of the receiver R-648/ARR-41 and its mounting, is a radio receiver that finds general application in naval aircraft. It is a superheterodyne receiver capable of receiving RF signals from 190 kHz to 550 kHz and from 2 MHz to 25 MHz, covered in five frequency bands. A mechanical type counter, located on the front panel of the receiver, indicates the frequency (in megahertz) of the received signals. It can receive signals which are of the AM, unmodulated CW, or frequency shift keyed types. Accurate frequency calibration is obtained through a built-in circuit consisting of a 500 kHz crystal-controlled oscillator and a multivibrator. Construction is of the subassembly design.

The Service Instruction Manual for the receiver presents in detail the theory and operation of the receiver, the maintenance, test, and alinement procedures and specifications, and the complete list of test equipment required. Only a brief summary of the theory of operation of the (R-648) ARR-41 is presented in this chapter.

Theory of Operation

This receiver employs double conversion; that is, all received RF signals (except for band 2) are first converted to a variable IF, amplified, and then converted to a fixed IF. (Band 2 covers the range of 2 megahertz to 4 megahertz; signals within this band are shunted around the first converter, or mixer.) Some of the benefits obtained by double conversion are high gain and sensitivity.

For CW reception the set employs a beat frequency oscillator (BFO), with a control for variable pitch or tone. A CW signal contains no modulation, so a separate oscillator must be built into the receiver in order to receive CW. The principle of the BFO is discussed in Basic Electronics, NavPers 10087-B.

Figure 16-15 is a block diagram of the receiver. Reference to this diagram, in connection with the discussion that follows, simplifies the explanation of the receiver's operation. Particular attention should be paid to the direction of the arrows.

13636

UNIT V - TRACING

The Ruling Pen Lesson 1

OBJECTIVE: To learn how to correctly use and maintain a ruling pen.

RELATED INFORMATION:

Every prospective draftsman should learn how to use and care for inking instruments. More than likely, some of the first work he encounters will have to be done in ink. Although inking doesn't hold the prominent position it once maintained in the drafting field due to its cost, many industries still have all or a portion of their drawings inked.

FIG. 1

The ruling pen (Fig. 1) is used for inking straight lines and non-circular curves. A pen in poor condition will render sloppy, dull lines, whereas a properly sharpened, clean pen makes sharp, clear lines. Every draftsman must learn to keep his pens clean and well sharpened. This can be achieved by wiping them clean with a moist rag and sharpening them when required on an oilstone.

The ruling pen is always used in connection with a guiding edge, T-square, triangle, straightedge or curve. The T-square and the triangle should be held in the same postions as for penciling.

FIG. 2

The incoming RF signal is received by the antenna and applied to one of five tuned circuits, depending upon the band of reception. The signal is then applied to the grid of the first RF amplifier, V701, for amplification. After the first stage of RF amplification, frequencies within the range of bands 1, 3, 4, and 5 are applied through tuned circuits to the second RF amplifier and then through more tuned circuits to the first mixer, V703. The function of the first mixer is to heterodyne the output of the RF oscillator, V601, with the incoming RF and produce a variable IF of 2 MHz to 4 MHz. Band 2 frequencies are 2 MHz to 4 MHz without heterodyning and therefore are switched around the second RF amplifier and first mixer circuits. (The switches in the block diagram are shown in band 2 position.)

At this point, any signal, regardless of the original frequency, is within the range of 2 MHz to 4 MHz and is applied through the variable IF tuned circuits to the variable frequency oscillator converter, V15001. Mixer V15001 heterodynes the variable IF 2 MHz to 4 MHz signal with a locally generated 2.5 MHz to 3.5 MHz signal, producing an output of 500 kHz, the fixed intermediate frequency.

AT.292

Figure 16-15.–Block diagram of Radio Receiver R-648/ARR-41.

13637

The 500 kHz signal is applied to the grid of V501 for first IF amplification. This output passes through either a broad band or narrowband mechanical filter (fully explained in chapter 16 in connection with single sideband) and through one of two second IF amplifiers. Bandwidth selection (broad or narrow) depends upon the setting of the emission switch. The IF signal is then applied through another tuned circuit to the grid of the third IF amplifier, V504, the plate circuit of which contains the IF tuned circuit Z504. Tuned circuit Z504 couples the output of IF amplifier V504 to the detector tube V505. The functions of V505 are to recover the modulation component of the IF signal (detection) and to produce a negative voltage proportional to the carrier level for automatic volume control (AVC).

The BFO may be switched into the detector input by operation of the emission switch to the CW or CW SHP positions. In this manner a beat note is produced with the 500 kHz IF signal, which is a variable tone to be used for CW reception. Output from the detector is applied to V506, the limiter and AVC gate. One-half of dual diode V506 functions as an AVC gate control and prevents application of AVC voltage to the various amplifiers until full receiver sensitivity has been reached. The other half of V506 is a noise limiter which suppresses undesired noise pulses. The output of V506 is an audio voltage proportional to the modulation of the incoming RF signal. Audio amplifier V1301 and audio output V1302 serve to amplify the audio signal. Phone jack J303 is connected to audio output transformer T1301, and is available on the front panel of the receiver.

The spectrum generator consists of a crystal-controlled oscillator and a multivibrator divider circuit. The crystal-controlled oscillator, V750, serves to produce an accurate 500 kHz signal. The 500 kHz signal is applied to the grid of the first IF amplifier, V501, and to one plate and grid of the multivibrator divider, V751. The multivibrator fires on every fifth input pulse and produces an output, to the first RF amplifier, of 100 kHz. This 100 kHz output signal is rich in harmonics and allows the RF circuits to tune to a particular harmonic, depending upon the resonant frequency of the tuned circuits. A beat note is produced as a result of heterodyning the 500 kHz signal applied to the first IF amplifier with the selected harmonic of the multivibrator. This beat note is heard when the receiver frequency is varied around the selected multivibrator harmonic and the correct receiver frequency is known on the basis of the counter reading. The counter may then be set to the exact 100 kHz multiple and calibration is completed.

Operation

Complete details regarding the operating procedures of the AN/ARR-41 are contained in the Operation Instruction Manual, NavAer 16-30ARR41-501. This discussion is presented only to provide a few details concerning capabilities of the receiver.

The emission selector switch has two positions which are used when noise interferes with reception of voice or CW signals. By switching to either of these two sharp positions, a narrowband filter is inserted into the IF circuit to reduce the effective noise level.

Selected frequency is indicated on three counter dials. Selected band is indicated on a fourth dial located immediately to the left of the frequency counters. Interpolation to within 0.1 kHz is made possible by the arrow located to the right of the right-hand counter.

Calibration and Maintenance

Calibration and maintenance procedures and specifications are contained in the Service Instruction Manual, NavAer 16-30ARR41-502. Organizational maintenance is made relatively easy and rapid because of the interchangeable subassembly type construction of the unit.

VHF TRANSCEIVER AN/ARC-44

Radio Set AN/ARC-44 is a subminiature airborne frequency modulated receiver-transmitter. It operates in the frequency range of 24.0 MHz to 51.9 MHz. Its primary function is to provide two-way voice communications between aircraft, or between an aircraft and ground stations. Normally, use of the equipment is limited to line-of-sight distances; by use of a retransmit feature (which requires a dual installation of AN/ARC-44) the equipment

13638

can serve as a radio relay, thus extending the operating distance. A second auxiliary function permits use of the equipment to home on any station within range. Another feature permits control of the other radio transmitters and receivers and the ICS equipment through the AN/ARC-44 control box switches.

The AN/ARC-44 is installed primarily in older type aircraft. It is not part of any specific integrated system, but is adaptable to almost any communication/navigation system in present use.

Input power requirement for the equipment is limited to 27.5 volts d.c. from the main aircraft supply. A dynamotor is used to convert the input power into +150 volts d.c., -150 volts d.c., and 27 volts 400 hertz single-phase a.c. These output voltages are then distributed to the appropriate circuits throughout the equipment.

Interunit connecting wiring is primarily of the cable harness type. Multiple-pin receptacles are mounted on each unit and mounting rack, with a central terminal box used to terminate the other end of each cable. Necessary connections are made within the terminal box.

Cooling of the main receiver-transmitter unit is accomplished by means of an exhaust air blower. Air leaks into the unit from its immediate surroundings, the air is heated by the operating equipment, and is then exhausted back into the space surrounding the equipment.

Double-conversion superheterodyne circuits are used in conjunction with the receiver circuits to change an incoming modulated RF signal in the range of 24.0 MHz to 51.9 MHz to a modulated IF signal of 2.9875 MHz; they are used in conjunction with the transmitter circuits to change a modulated 2.9875 MHz oscillator signal to a modulated RF output between 24.0 MHz to 51.9 MHz. In each case, the change is accomplished in two mixer stages.

Frequency modulation of the transmitted signal is accomplished by use of a reactance tube modulator and a "sidestep" oscillator. These stages produce a 2.9875 MHz carrier which is modulated by the incoming audio signal. (See fig. 16-16.)

The sidestep oscillator is a Lampkin type oscillator. It employs a free-running, temperature compensated circuit and operates at a center frequency of 2.9875 MHz. The oscillatory tank circuit consists of L1703 and C1707, together with trimmer C1708. The portion of L1703 between C1705 and a-c ground (at the top of C1706) is common to both the plant and grid circuits. It is through this common path that regenerative feedback occurs continuously.

One side of C1708 is placed at a-c ground potential to facilitate mounting of this capacitor. The tuning range of C1708 is determined by the position of the L1703 tap for feedback coupling capacitor C1705. Resistor R1706 is the grid leak resistor.

The advantage of this type of oscillator is that variations which occur in tube characteristics have a minimum effect on the tank circuit frequency. Temperature compensation within the tank circuit is achieved by making the end plate of C1707 from a bimetallic material. Any variations in tank coil inductance produced by temperature variations will be compensated by capacitance variations in C1707.

RF voltages appearing across the oscillator tank also appear across the phase shifting network in the modulator input by way of d-c blocking capacitor C1710. This network consists of resistor-capacitor combinations R1709/C1709 and R1712/C1711 plus the internal resistance (plate-cathode circuit) of V1703. The voltage drop across C1711, by reason of the phase-shifting network, lags the tank voltage by 90°. Since the modulator RF plate current responds in the same phase as the grid voltage, it also lags the tank voltage by 90°. The RF plate current flows through the tank circuit and vectorially adds with the current therein to produce a resultant current differing in phase from the original tank current. This is equivalent to adding a reactance to the oscillator tank or, in other words, to changing the oscillator frequency.

Because of the phase difference existing between the modulator plate current component and the original oscillator tank current component, the phase of the resultant current depends on the magnitude of either of these out-of-phase components. This characteristic is used to produce the frequency modulation.

Audio voltages applied to the control grid of the modulator change the magnitude of the RF plate current in direct proportion to the audio voltage swing. Thus, due to the changing RF plate current components, the phase of the resultant tank current (and the frequency of the

13639

AT.293

Figure 16-16.–Reactance modulator and sidestep circuits.

oscillator) varies in accordance with the amplitude variations of the audio signal.

Selection of operating frequency is accomplished through use of a tuning drive mechanism, which automatically adjusts the appropriate stages of both the receiver and transmitter.

Additional details concerning Radio Set AN/ARC-44 may be found in NavWeps 16-30ARC-44-1.

SINGLE SIDEBAND TRANSCEIVER AN/ARC-94

Radio Set AN/ARC-94 provides facilities for communication between aircraft, and between aircraft and fixed or mobile ground communications stations. The AN/ARC-94 transmits and receives communications in the high-frequency (HF) band and can operate over the 28 megahertz band between 2,000 megahertz and 29.999 megahertz. The set includes Radio Receiver-Transmitter RT-648/ARC-94, Radio Set Control C-3940/ARC-94, and Mounting MT-2641/ARC-94. The RT unit is of modular construction for ease of maintenance. In addition to the set components, the complete aircraft installation requires a headset, microphone, key, antenna coupler, and antenna.

The RT unit functions as a part of an overall HF communications system. Frequency

13340

selection is in increments of 1 kHz over the entire band, providing a choice of 28,000 operating frequencies.

The control unit provides for remote selection of operating frequency, and for selection of upper sideband, lower sideband, amplitude modulation, data link, or CW mode of operation.

The mounting provides for mechanical support and isolation from airframe vibration and shocks.

Operation of the set, as discussed briefly in the following paragraphs, is divided into a transmit function, a receive function, and a carrier generator function which is common to both reception and transmission. The brief discussion is in block diagram form. (Refer to fig. 16-17 in connection with the discussion.) Principal intelligence signal flow is indicated by heavy lines.

The diagram is divided functionally rather than by the physical location of the parts.

AT.294

Figure 16-17.–AN/ARC-94, simplified block diagram.

Blocks and individual component parts mentioned in the discussion are referenced in the standard manner for modular construction. Modules are referenced as A1, A2, etc. Where detail parts are considered in a discussion, the module designation and the part designation are combined into a compound reference, such as A1R2, A2R2, etc., to indicate the module and specific part. Parts located on submodules are designated by a triple compound designation such as A12A2C3, where A12 is the module, A2 is the submodule, and C3 is the detail part of interest.

Transmit Function

The transmit function includes an AF input section, an IF translator section, an RF translator section, and a power amplifier section.

The AF input section provides coupling and amplification for the voice intelligence to be transmitted. The IF translator section contains the circuitry for selecting the desired mode of operation and the stages that modulate and process the desired signal accordingly. The RF translator section performs the final conversion

AT.294

Figure 16-17.–AN/ARC-94, simplified block diagram–Continued.

13642 L43C1

step in translating the modulated signal information to the frequency band selected for transmission. The carrier generator function provides all the frequencies required for the double conversion transmit function The carrier generator function also provides all the frequencies required for demodulating in the receive function. Tuning is carried out within the carrier generator function by means of an autopositioner system similar to that of the AN/ARC-88.

AF INPUT SECTION.–An audio signal from the operator's microphone, fed into the 100-ohm, unbalanced input, is amplified in audio amplifier stages A9Q1 and A9Q2 and applied to the balanced modulator in the IF translator section.

When a 600-ohms balanced audio input is used, the signal is preamplified by audio amplifier A9Q8 before being applied to A9Q1 and A9Q2.

When the transmitter is operating in the CW mode, a 1 kHz audio signal is obtained from frequency divider module A1. This 1 kHz signal is then fed from CW keying relay A9K1 to the audio input.

IF TRANSLATOR SECTION.–The audio signal from the AF input section and a carrier signal from locked oscillators A2Q4 and A2Q8 in the carrier generator function are combined in the balanced modulator. The balanced modulator yields a suppressed carrier amplitude modulated output consisting of upper and lower sidebands. The balanced modulator output is fed to automatic load control A3Q1, which is controlled by a signal fed back from the power amplifier in the power amplifier section. The output level of the automatic load control stage is adjusted by the feedback voltage to maintain the transmitter output at a predetermined level. From A3Q1, the signal is applied to A3Q2 through relay A3K5. The desired signal is then amplified by IF amplifier A3Q2 and applied to the mode selector.

The mode selector provides the option of operating in either SSB, AM, data, or CW mode. In SSB mode, the further option of using USB or LSB is provided.

In AM mode, the double-sideband suppressed carrier signal is applied to 3 kHz mechanical filter A3FL1, which passes only the upper sideband. A 500 kHz carrier signal from the carrier generator function is reinserted into the upper sideband at the output of filter A3FL1.

In SSB mode, the carrier reinsertion capability is disabled. The double-sideband suppressed carrier output of A3Q2 is switched to a 3 kHz mechanical filter, either A3FL1 or A3FL2, depending on the setting of the mode selector. Filter A3FL1 passes only the USB and A3FL2 passes only the LSB. The sideband not passed is suppressed. An intelligence consisting of a USB or LSB signal is then fed through relay A3K5 to IF amplifier A3Q4.

The data and CW modes are similar in function to the SSB modes since USB is always used for data and CW operation.

The desired signal is amplified in A3Q4 and fed to transmit LF mixer A12V1. Transmitter gain control amplifier A3Q6 controls the output transmission level by adjusting the gain of A3Q4 in accordance with control voltages provided in the form of a transmitter gain control signal and an automatic drive control signal.

RF TRANSLATOR SECTION.–The desired signal is mixed in A12V1 with a preselected output from the variable frequency oscillator in the carrier generator function. The output circuit of A12V1 is tuned to the difference frequency of the two signal inputs to the mixer. The frequency range of the output signal from the transmit LF mixer is 2.001 MHz to 3.000 MHz in 1 kHz increments. If the selected output frequency is to be in the range of 2.0 MHz to 6.999 MHz, the LF mixer output signal is coupled to transmit 17.5 MHz mixer A12V2. A signal is also applied to A12V2 from 17.5 MHz oscillator A12V10. The output circuit of A12V2 is tuned to the difference frequency of the two signals to produce an output frequency in the range of 14.5 MHz to 15.5 MHz. If the selected output frequency is to be in the 7.0 MHz to 30.0 MHz range, the output of A12V1 is coupled directly to A12V3. A signal is also applied to A12V3 from HF oscillator A12V11. The difference frequency of the two input signals mixed in A12V3 is at the desired output frequency and is amplified by RF amplifiers A12V4 and A12V5 and fed to drivers A12V6 and A12V7. The driver output is fed to power amplifiers A11V1 and A11V2.

POWER AMPLIFIER SECTION.–The power amplifier is band-switched by the autopositioner and tuned by a servo-driven inductance in electronic control amplifier module A6. The output

13643 1965

of the power amplifier is designed for a 52-ohm unbalanced load and is applied to the transmitting antenna through an antenna coupler.

Receive Function

The receive function includes an RF input section, a first and second conversion section, an SSB channel, an AM channel, and an audio section.

The RF input section receives the desired signal broadcast by the remote station. The signal is amplified and sent to the first and second conversion sections, where a double conversion is performed to bring the signal to the desired intermediate frequency. In SSB, data, and CW modes, the AM channel is disabled and the desired signal is brought to the SSB channel. After being amplified to a suitable level, the desired SSB signal is demodulated in a product detector. The resultant audio signal is amplified in the audio section and applied to headset phones.

In AM mode, the SSB channel is disabled and the desired signal is brought to the AM channel. In the AM channel, a standard AM detector is used to demodulate the signal. All other functions are similar to those which occur in the SSB channel.

COMMON STAGES.–The receive function of the AN/ARC-94 uses many stages in common with the transmit function. Function selection is controlled by the operator with a push-to-talk switch. When the switch is operated, the transmit function is actuated. At all other times the receive function is actuated. A relay operated switching system shifts the assignments of the common stages between transmit and receive functions as required.

RF INPUT SECTION.–The RF input section receives the desired signal from a remote station. The impedance of the antenna is matched to that of amplifiers A12V4 and A12V5 by a suitable coupler device to insure maximum energy transfer. The amplifiers step up the received signal and apply it to receive HF mixer A12V12 in the first conversion group. RF gain is manually adjustable from the C-3940/ARC-94. The RF amplifiers are also under AGC system control.

CONVERTER SECTION.–The output of A12V4 and A12V5 is fed to receive HF mixer A12V12 where it is mixed with the signal from HF oscillator A12V11 in the carrier generator section. The output of A12V12 is coupled to receive 17.5 MHz mixer A12V9 if the operating frequency is in the range of 2.0 MHz to 6.999 MHz. It is coupled to receive LF mixer A12V8 if the operating frequency is in the range of 7.0 MHz to 30.0 MHz. The output from A12V8 is a 500 kHz IF signal. The 500 kHz IF signal is fed to either the SSB or AM channel.

SSB AND AM CHANNELS.–In SSB mode, the 500 kHz IF signal is applied to one of two mechanical filters, A3FL1 or A3FL2. Each mechanical filter has a bandwidth of 2.7 kHz. One filter passes the upper sideband, and the other passes the lower sideband. The appropriate filter is selected at the mode selector on the C-3940/ARC-94. The filter output is amplified in IF amplifiers A3Q3, A3Q4, and A3Q5. The output of A3Q5 is applied to product detector A3CR5 which recovers the audio signal.

In AM mode, the output of A12V8 is fed to IF amplifier A9Q3 for amplification and is coupled to 6 kHz mechanical filter A9FL1. The signal is then fed to three more IF amplifiers, A9Q4, A9Q5, and A9Q6. The output of A9Q6 is fed to diode detector A9CR4 which recovers the audio signal and applies it to the audio section.

AUDIO SECTION.–In either channel, the desired audio signal is amplified in audio amplifiers A9Q1, A9Q8, and A9Q2, and fed to the operator's headset. Selcal (selective calling) signals detected in AM detector A1CR4 are fed to audio amplifier A9Q9 and are coupled to the rear connector of the RT-648/ARC-94. Selcal signals are detected in all modes of operation.

Carrier Generator Function

The carrier generator function includes RF oscillator A2, frequency divider A1, kilohertz-frequency stabilizer A4, variable frequency oscillator (VFO) A12A2, 17.5 MHz oscillator A12V10, megahertz-frequency stabilizer A10, and HF oscillator A12V11.

FREQUENCY GENERATION AND STABILIZATION.–The AN/ARC-94 transmits and receives on every 1 kHz increment from 2,000 MHz to 29.999 MHz. This provides 28,000 possible separate operating frequencies. The operating frequency is selected at the C-3940/ARC-94. The 100 kHz, 10 kHz, and 1 kHz fre-

13644

quency selector knobs on the C-3940/ARC-94 actuate autopositioner A12A1. The autopositioner mechanically tunes variable frequency oscillator A12A2 over the range from 2.501 MHz to 3.500 MHz in 1 kHz increments. The megahertz frequency selector knob on the C-3940/ARC-94 controls a motor in RF translator module A12. This motor switches tuning elements which tune HF oscillator A12V11 to one of 28 different frequencies. The HF oscillator, in conjunction with 17.5 MHz oscillator A12V10, provides 28 1 MHz bands for each of the 1 kHz increments from variable frequency oscillator A12A2.

Megahertz-frequency stabilizer module A10 stabilizes the frequency of A12V10 and A12V11 by comparing each oscillator frequency with the frequency of a spectrum point derived from the 500 kHz output of RF oscillator module A2. The coarse frequency of A12V11 is controlled by the motor in RF translator module A12. The frequency range of A12V11 is 8.5 MHz to 32.0 MHz. The output of A12V11 is tuned to the second harmonic of the fundamental oscillator frequency when the selected operating frequency of the RT-648ARC-94 is in the range of 14.0 MHz to 29.999 MHz. This signal is coupled to transmit HF mixer A12V3, and to receive HF mixer A12V12.

The extremely high stability of the AN/ARC 94 operating frequency is obtained by basing frequency control of the entire RT-648/ARC-94 on the frequency of a very stable crystal oscillator located in RF oscillator module A2. Frequency stability of this crystal oscillator is assured by utilizing a temperature-compensating network.

The HF and 17.5 MHz oscillators are frequency locked, and the variable frequency oscillator is phase locked to the crystal generated reference frequency by circuits in the megahertz- and kilohertz-frequency stabilizer modules. The IF injection frequency is derived from the crystal oscillator. The RT-648/ARC-94 operating frequency is thus held accurate within ±0.8 part per million per month from -40° C (-40°F) to +75°C (+167°F).

Keying Circuits

When the RT-648/ARC-94 is keyed, the keying circuits actuate the stages that must operate if the RT-648/ARC-94 is to transmit, while disabling receiver circuits that would interfere with transmission. When the key is released the keying circuits operate to switch off the transmitter and switch common stages from the transmit to the receive function.

Sidetone Circuits

The sidetone signal is taken from audio amplifier stage A9Q2 to provide audio monitoring in the transmit mode. The audio signal from the audio amplifier is fed through a keying relay and a sidetone relay (not shown) to the audio output. A combination of two voltages is used to energize the sidetone relay.

One voltage is derived from the RF output of power amplifier module A11. This RF output is rectified, filtered, and applied to the sidetone relay coil.

The second voltage, from three-phase high-voltage power supply module A7 (not shown) is proportional to the power amplifier plate current. This voltage is the same one used for transmitter gain control in IF translator module A3. To energize the sidetone relay, sufficient plate current and plate voltage swing must be present in the power amplifier. A capacitor is placed across the coil of the sidetone relay to keep the relay energized in the sideband transmit mode when the plate current varies with the applied audio signal.

Recycle Circuits

The recycle circuits are activated when any of the frequency selector knobs on the C-3940/ARC-94 are turned. When any autopositioner operates, the recycle relay (not shown) is energized, and remains energized so long as any tuning motor is operating. The recycle relay has the following functions:

1. Disconnects transistor supply voltage to the audio amplifier in order to mute the audio during the tuning cycle.
2. Provides a ground to activate the antenna tuner.
3. Interrupts the operation of kilohertz-frequency stabilizer module A4 during the tuning cycle.

13645

4. Disconnects the keying circuit so that the transmitter cannot be keyed during the tuning cycle.

UHF TRANSCEIVER (FM) AN/ARC-88

The purpose of Radio Set AN/ARC-88 is to provide a UHF frequency-modulated radio link between aircraft, shore, and ship. Radio Receiver-Transmitter RT-649/ARC-88 is a partially transistorized equipment capable of transmitting and receiving on any one of 1750 frequency channels, spaced at 100 kHz intervals in the 225.0 MHz to 399.9 MHz range. The equipment receives and transmits multiplexed data information originating in the form of digital pulses from an associated equipment of a digital data communication system.

Radio Set AN/ARC-88 is supplied digital information from the associated data equipment and transmits it on a frequency modulated carrier signal. It also receives a similar frequency-modulated signal, demodulates the signal, and supplies the resulting pulses to the associated data equipment. Reception and transmission are on the same frequency and utilize the same antenna.

Radio Set Control C-2736A/AR provides remote selection of the 1750 frequency channels or 19 preset channels within the specified range. (The frequencies of the 19 preset channels are determined by adjustment of a memory drum on the front panel.)

Major Components

Radio Set AN/ARC-88 consists of Radio Receiver-Transmitter RT-649/ARC-88, Mounting MT-2653/ARC, Standing Wave Ratio Indicator IM-178/ARC-88. Electronic Equipment Air Cooler HD-513/ARC, and Radio Set Control C-2736A/AR. The following paragraphs provide a brief description of these components, followed by a brief discussion of the general principles of operation of the equipment.

RECEIVER-TRANSMITTER.–Radio Receiver-Transmitter RT-649/ARC-88 consists of a main chassis, dust cover, and nine plug-in modules. The nine plug-in modules are mounted on the main chassis and enclosed in an aluminum case. An airtight seal is provided between the cover and the main chassis to permit the modules of the component to be pressurized. External cooling air is forced by the external blower through the base casting to the heat exchanger and expelled at the bottom of the unit. (See fig. 16-18.) Internal air is circulated through the internal cores of the heat exchangers, through the plenum chamber formed by the main chassis, and through each module by an internal blower. In this manner, the heat from the component is dissipated.

An antenna, two power connectors, and a pressurizing valve are mounted on the front panel. A toolkit containing special tools for maintenance is supplied with Radio Receiver-Transmitter RT-649/ARC-88.

MOUNTING.–Mounting MT-2653/ARC provides a mounting base for Radio Receiver-Transmitter RT-649/ARC-88. Vibration isolators which are usually a part of the mounting are an integral part of the mounting base casting of the RT-649/ARC-88.

SWR INDICATOR.–Standing Wave Ratio Indicator IM-178/ARC-88 provides the operator with a remote indication of transmitter power output. It is secured to the front panel of the RT unit by three cross-recessed screws. When the set is in transmit operation, the remote meter indicates incident power. By changing the connection of the remote power indicator to the other wire on the multiwire cable, a reflected power measurement may be obtained.

AIR COOLER.–Electronic Equipment Air Cooler HD-513/ARC is made up of a casting, single-phase blower motor, and an air inlet filter assembly. It is secured to the rear of the RT unit by four hex-socket screws. The HD-513/ARC operates when the internal temperature of the RT unit exceeds 35°C (95°F).

CONTROL UNIT.–Radio Set Control C-2736/AR is used to control Radio Receiver-Transmitter RT-649/ARC-88. A selector switch on the front panel makes 19 preset channels available to the operator. This selector switch has complete control of selection unless it is set to the M position. In the M position, adjustment of the four MANUAL frequency controls operates switches which activate an autopositioner, located in the RT unit, to set up operation at the selected frequency. A three-position rotary power switch on the front panel controls

13646 1406L

To fill the pen, take it to the bottle and touch the quill filler between the nibs, being careful not to get any ink on the outside of the blades (Fig. 2).

The pen should be held in the fingertips, as shown in Fig. 3. The position shown aids in keeping the pen at the proper angle and the nibs aligned with the ruling pen. If the ink refuses to flow, it may be because it has dried in the extreme point of the pen. If pinching the blades slightly does not start the flow of ink, the pen should be immediately wiped out and fresh ink supplied. Always wipe pens clean after using.

FIG. 3

QUESTIONS:

1. Why doesn't industry in general ink more drawings?
2. What is the best way of keeping a ruling pen clean?
3. What type of stone should be used for sharpening a pen?
4. If you are drawing dull ink lines, what does this indicate?
5. Can circles be drawn with a pen?

the power on-off and the selection of the associated radio equipment. Frequency adjustments for preselected channels are made by lowering a small panel at the bottom of the front panel.

Principles of Operation

Radio Receiver-Transmitter RT-649/ARC-88 is a remotely controlled receiver and transmitter which makes use of the double-conversion superheterodyne principle. Two sources of injection frequencies are heterodyned with the signal input during receiving operation, or heterodyned with a developed carrier during transmitting operation, to produce the desired intermediate frequencies. (See fig. 16-19.)

The higher injection frequencies are developed in the spectrum generator module and are in the 200 MHz to 370 MHz range. The fundamental signals are produced by a crystal oscillator, fed through a frequency multiplier, amplified, and then applied to the first receiver mixer or the second transmitter mixer stage.

The lower injection frequencies in the 21.85 MHz to 31.75 MHz range are produced in the oscillator stages of the 20-30 MHz IF am-

13647

Figure 16-19.—AN/ARC-88, simplified block diagram.

13648

plifier module by mixing the output of two crystal oscillators. One of these oscillators provides an output in the range of 24.9 MHz to 33.9 MHz and the other 2.15 MHz to 3.05 MHz. The heterodyne difference frequency in the 21.85 MHz to 31.75 MHz range is amplified and applied to the second receiver mixer or to the first transmitter mixer stages. Relays accomplish circuit switchover from receiver to transmit operation.

The crystal-controlled frequency generation and injection systems are ganged mechanically to the tuning mechanism of the RT unit. All tuning or channeling is accomplished by the mechanical tuning module, in response to Radio Set Control C-2736A/AR.

The received signal, consisting of a frequency shift keyed carrier within the range of 225.0 MHz to 399.9 MHz, is fed from the antenna through an antenna relay into the amplifier circuits of the receiver RF preamplifier module, and applied to an RF amplifier circuit of the power amplifier module. In the power amplifier module, the received signal is further amplified and mixed with the 200 MHz to 270 MHz injection voltage output of the spectrum generator module. The resultant 20.0 MHz to 29.9 MHz first intermediate frequency is applied to the 20-30 MHz IF amplifier module where it is mixed with the 21.85 MHz to 31.75 MHz output from the two crystal oscillators within the 20-30 MHz IF amplifier module. The heterodyned difference between the first intermediate frequency and the output from the 20-30 MHz IF amplifier module crystal oscillators is mixed in the 20-30 MHz IF amplifier module to produce the 1.85 MHz second intermediate frequency. This output is fed through a 1.85 MHz filter, four stages of IF amplification, and two limiter stages to a discriminator. After demodulation, the data signal is amplified in two d-c amplifier stages and fed to the associated data equipment.

The operation of transfer relays and electron tube switching, from receive to transmit or from transmit to receive operation, is accomplished by the transmit keyer module in response to data input signals from the associated data equipment.

During transmission, the initial excitation is obtained from a frequency modulator and oscillator in the FM detector-oscillator module which operates at a center frequency of 1.85 MHz and is frequency modulated with the data information furnished from the associated data equipment. The 1.85 MHz frequency-modulated signal is mixed with the 21.85 MHz to 31.75 MHz injection signal from the two crystal oscillators within the 20-30 MHz IF amplifier module. The heterodyned difference between the 1.85 MHz signal and the oscillator injection signal produces the 20 MHz to 29.9 MHz intermediate frequency. The 20 MHz to 29.9 MHz intermediate frequency is fed through two stages of amplification in the 20-30 MHz IF amplifier module and mixed in the second transmitter mixer stage of the receiver RF preamplifier module with the 200 MHz to 370 MHz injection output from the spectrum generator module. The resultant carrier frequency of 225.0 MHz to 399.9 MHz is then fed through two stages of amplification in the receiver RF amplifier module, three stages of amplification in the power amplifier module and applied to the antenna.

Channel Selection

The set contains provisions for either automatic or manual selection of the operating frequency channel. Selections of channeling mode and operating frequency are made at the control unit. Actual tuning is accomplished by mechanical linkages in the mechanical tuning module.

Both automatic and manual channel selection are accomplished by tuning the tank circuits of the receiver RF preamplifier, power amplifier, 20-30 MHz IF amplifier, and spectrum generator modules for reception or transmission on the selected frequency.

In regard to channel selection, the terms automatic and manual are used to differentiate between the selection of one of 19 preset channels by rotating the channel selector switch and the selection of one of 1750 frequency channels by individual setting of the manual frequency controls. In either case, the actual mechanical and electrical tuning operations within the equipment are fully automatic.

Selection of any frequency is initiated when the operator rotates the decade selector to the desired frequency. By rotating a particular decade selector, the switch circuit that corresponds to the new frequency setting is grounded. By grounding the switch circuit, the positioning system of the mechanical tuning module is energized and produces a synchronized

10059

rotation of the gear train in the prescribed direction by a predetermined amount. The motion imparted to the gear train automatically adjusts the module tuned circuits for operation of the equipment on a selected frequency.

A simplified positioning system to illustrate the principle is shown in figure 16-20. The selector switch (remote control switch) chooses the operating frequency, and the seeking switch determines the angular position to which the drive motor rotates the shaft for a specific selected frequency. As shown, the equipment is at rest with the selector switch and the seeking switch at position 1. When the switches are at the corresponding position, no contact of the seeking switch is grounded through the selector switch; the electrical circuit of the drive motor is broken by the open motor control contacts of the deenergized relay.

The drive motor, which has driven the seeking switch to rest at position 1, has also driven the module tank circuits to the selected frequency in the same angular rotation.

Assume the selector switch is rotated so that the tab of the selector contacts the terminal at position 2. A closed path to ground then is completed from the +27.5-volt supply through the relay coil, the common contact and contact 2 of the seeking switch, through contact 2 of the selector switch, and to ground through the common contact of the selector switch. Relay K1 is energized and closes the motor control contacts; the drive motor then rotates in the predetermined direction. The seeking switch, which is geared to the drive motor, is driven until the cutout of the seeking switch is adjacent to position 2. At this position, the 27.5-volt path is opened, the relay releases, the motor stops, and the system comes to rest. Since the seeking switch and the tuned circuits are gear-driven by the motor, the tuned circuits are driven through the required angular displacement, which is proportional to

AT.297

Figure 16-20.–Automatic positioning, functional diagram.

13650

the seeking switch travel from position 1 to position 2.

As illustrated in figure 16-20, the switch arrangement includes a notched stop wheel and pawl that accurately positions the seeking switch as soon as the drive motor is deenergized, and a clutch that decouples the switches from the drive motor and gear train when the final position is reached. Although not shown in figure 16-20, the clutch permits a single motor to drive several seeking switch shafts.

Assume the selector switch is rotated so that the circuit having the increments of the selected frequency is grounded. A complete path to ground is provided from the 27.5-volt supply through the relay coil, the seeking switch, the applicable control wire, and the selector switch. The actuated relay withdraws the pawl from the notch along the periphery of the stop wheel and energizes the drive motor through the closed motor control contacts of the relay.

The subsequent rotation of the drive motor, which is in a predetermined direction, drives the gear train, clutch, stop wheel, and seeking switch. The motor rotation is continuous until the motor (and tuning gear train) has rotated through the required tuning angle; at this point, the corresponding contact of the seeking switch is open, breaking the path to ground from the 27.5-volt supply. The relay releases, permitting the pawl to engage a stop wheel notch at which time the motor control contacts open. The subsequent loss of stop wheel motion brakes the seeking switch and shaft. The kinetic energy of the drive motor (which persists after the removal of the drive motor source power) is dissipated in the gear train and clutch. At rest, the seeking switch and shaft are in a position synchronous with the position of the selector switch.

In actual practice, to insure proper positioning of the stop wheel, the seeking switch opens the relay circuit shortly before the stop wheel reaches the notch to be engaged by the pawl. The relay motor control contacts are operated mechanically by the pawl arm so the contacts remain closed until the pawl drops into the prescribed notch.

The channel selector circuits of Radio Receiver-Transmitter RT-649/ARC-88 and Radio Set Control C-2736A/AR are more complex but use the principles of the single selector-seeking system shown in figure 16-20. The actual system, however, employs three selector-seeking switch groups which are driven by a single motor. (Refer to figure 16-21.) Each of the three groups has individual switch connections, relay, pawl, stop wheel, and relay motor contacts.

The seeking switches are driven by the motor through three separate friction type slip clutches, one of which is attached to each of the three primary shafts. When a pawl is not engaged in a stop wheel notch, the tension in the clutch spring is sufficient to allow the motor to turn the seeking switch shaft. When the stop wheel is held by the pawl, the motor side of the clutch can rotate while the seeking switch side of the clutch remains motionless. Several seeking switch shafts thus may be independently positioned by a single drive motor and gear system.

The channel selector system is, essentially, a three-section decade system that allows two alternative methods of inserting a different frequency setting: automatic, wherein any one of 19 preset channels may be selected by the channel selector switch, and manual, wherein any one of 1750 channels may be selected by means of four separate decade selectors, each of which must be set up individually for the frequency increment within its range. The two methods may both be subdivided into four parts consisting of the 200 MHz to 300 MHz, 10 MHz, 1.0 MHz, and 0.1 MHz decade selectors.

AUTOMATIC COMMUNICATIONS RELAY AN/ARC-52

Radio Set AN/ARC-52 provides two-way, amplitude-modulated radiotelephone communication (A-3) between aircraft in flight, aircraft and shore, and aircraft and ship. It is capable of transmitting and receiving on any one of 1750 manually selected frequency channels, spaced at 100 kHz intervals, in the band of 225.0 MHz to 399.9 MHz. It also permits the selection of any one of 18 preset channels within the specified frequency range, or the guard channel, which may be monitored on the predetermined frequency of 243.0 MHz. Auto relay is an alternate mode of operation which makes possible automatic communication relay operation.

13651

Two receiver-transmitter units operate identically and are completely interchangeable providing correct input power is present. The only difference between the two receiver-transmitters is the input power required. Receiver Transmitter RT-332/ARC-52 requires both a-c and d-c power, while Receiver-Transmitter RT-424/ARC-52X requires only d-c power.

Unless otherwise noted, Auto Relay Control C-2791/ARC may be used interchangeably where Radio Set Control C-1607/ARC-52 is referenced, and Receiver-Transmitter RT-424/ARC-52X is used interchangeably where Receiver-Transmitter RT-332/ARC-52 is referenced.

Automatic direction finding (ADF) operation is provided by the AN/ARC-52 when used in conjunction with Direction Finder Group AN/ARA-25. During ADF operation, the AN/ARC-52 receives RF signals from a direction finding antenna and delivers appropriate signal components to the direction finder amplifying and indicating equipment.

Emergency or direction finding (DF) operation is provided by a self-generated tone that occurs between 920 and 1120 hertz. The tone modulation (A-2) is a continuous signal, the interception of which may be used to locate the sending apparatus.

Automatic relay operation may be provided by two Radio Sets AN/ARC-52 connected in tandem between two prime stations. However, to provide this operation Auto Relay Control C-2791/ARC must be substituted for Radio Set Control C-1607/ARC-52 in at least one of the Radio Sets AN/ARC-52. When connected in this manner, an incoming signal received on one radio set is retransmitted automatically from the second radio set but on an alternate frequency. The range of the prime stations is thus extended since the automatic relay station effectively increases the line of sight between the two prime stations.

The intercom provision is an optional facility which can be connected for use as a

AT.298

Figure 16-21.–Mechanical tuning linkages.

13652

backup in case the separate intercom amplifier system of the aircraft fails. When operated in this mode, the transmit function is limited to the pilot only, unless special connections are included at the time of intercom installation.

Optimum performance may be attained through the use of either a carbon or a dynamic microphone, which provides a high degree of flexibility. A change of connections within the RT unit is required when a change from a carbon type microphone to a dynamic type microphone (and vice verse) is made.

The RT unit may be installed anywhere within the aircraft through Mounting MT-1477/ARC-52. Since installation is usually external to the pressurized aircraft cabin, the RT unit case has been pressurized. The pressurized case and relatively inaccessible location prohibits the replacement or repair of equipment parts while in flight. The control unit does not require a pressurized case.

RT-332/ARC-52 Unit

The RT-332/ARC-52 consists of a pressurized aluminum case, a main chassis, and 13 plug-in unit subassemblies (modules). The main chassis with mounted subassemblies, is enclosed in a double-walled, pressurized aluminum case which functions as a heat exchanger between the outside air and the air within the case. Air is forced between the walls of the case by a dual blower mounted on the front panel of the main chassis. The air is expelled through vents in the top of the case, thus dissipating the heat absorbed by the inner walls of the case. An axial-flow blower and a blower mounted on the a-c power unit circulate the air inside the case.

The modules, each of which is a functional entity, are comparatively accessible when the case is removed, so that module replacement may be used as an initial troubleshooting procedure. The mounting base for the modules is the main chassis, which provides the interunit electrical connections, plugs, jacks, and coaxial cables. The modules may be removed from the top of the main chassis by loosening the captive screws from the underside of the main chassis.

The front panel of the RT-332/ARC-52 contains the external blower and the antenna input jack. Headset and microphone jacks, test jacks, and sensitivity controls are located on the main chassis right-hand gusset plate. All jacks and controls on the gusset plate provide local maintenance facilities to the AN/ARC-52 repairman.

RT-424/ARC-52X Unit

The RT-424/ARC-52X is identical to the RT-332/ARC-52 except it contains only 12 plug-in unit subassemblies. The a-c power unit and rectifier unit used in the RT-332/ARC-52 are removed, and a new dynamotor power supply unit is installed in its place. Circulating air is provided by the internal blower motor of the dynamotor, and by an external d-c blower motor.

Radio Set Control C-1607/ARC-52

The C-1607/ARC-52 permits remote control of the RT-332/ARC-52 operation. These controls permit the selection of operational mode, volume control, frequency channel selection (channeling), and the means to set up and record the preset frequency channels.

Auto Relay Control C-2791/ARC

The C-2791/ARC performs all the functions of Radio Set Control C-1607/ARC-52 and additionally provides automatic relay (back-to-back) operation of two Radio Sets AN/ARC-52. The only visual difference between the radio set control and the auto relay control is the addition of an REL position to the function switch. By the addition of internal relays and the other component parts, the C-2791/ARC can place in operation two receiver-transmitters. Reception of a signal on the frequency of one receiver-transmitter will result in retransmission of the signal on the frequency of the other.

Principles of Operation

Radio Set AN/ARC-52 (fig. 16-22) is a remotely controlled transmitter and receiver unit equipped with all necessary control and mounting accessories. The transmitting and receiving components operate bilaterally; during reception the signal path is in one direction,

13653

AT.299

Figure 16-22.–AN/ARC-52 RT unit, block diagram.

13654 13652

during transmission the signal path is in the reverse direction.

The AN/ARC-52 has the greater sensitivity and the increased selectivity normally associated with double-conversion superheterodyne circuits. That is, an input signal is mixed with two separate but successive injection frequencies to obtain the desired intermediate frequency. Conversely, during transmission a basic frequency is mixed with the two injection frequencies to provide a carrier, the frequency of which is within the required range.

The received signal, which occurs in the 225.0 MHz to 399.9 MHz frequency range is applied to the RF amplifier and transmitter preamplifier module, where it is mixed with the 200 MHz to 370 MHz injection voltage output of the spectrum generator and amplifier module. The resultant 20.0 MHz to 29.9 MHz intermediate frequency is applied to the 20 MHz to 30 MHz IF amplifier module where it is mixed with the 21.85 MHz to 31.75 MHz injection voltage output of the oscillator module. The resultant 1.85 MHz intermediate frequency is filtered, amplified, and detected in the 1.85 MHz IF amplifier module and is then applied through the audio amplifier module to the headset.

The transmitter carrier is initiated within the oscillator module. The 21.85 MHz to 31.75 MHz output of the oscillator module is mixed with the 1.85 MHz signal in the 20 MHz to 30 MHz IF amplifier to produce a frequency of 20.0 MHz to 29.9 MHz frequency is applied to the RF amplifier and transmitter preamplifier module simultaneously with the 200 MHz to 370 MHz injection output of the spectrum generator and amplifier module. The resultant mixed carrier frequency of 225.0 MHz to 399.9 MHz is amplified and fed to the power amplifier module where it is modulated by the audio signals applied via the microphone and modulator module. The power amplifier module output, which passes through a 400 MHz low pass filter and terminates at the antenna, is a modulated carrier within the 225.0 MHz to 399.9 MHz frequency range. The modulated carrier is sampled by the sidetone detector of the antenna relay and applied to the audio amplifier module. This sidetone audio permits the operator to monitor the transmitted signal.

The guard receiver module is a single-frequency receiver which normally operates on a 243.0 MHz input frequency. The guard circuit is a double-conversion, superheterodyne type similar to the main receiver. Both receivers, however, work into a common audio output circuit.

The crystal-controlled injection systems, which are the sources of the beat frequencies, are ganged mechanically to the tuning mechanism of the AN/ARC-52 so that the selection of any frequency channels results in the development of a 20.0 MHz to 29.9 MHz and a 1.85 MHz intermediate frequency. All tuning, or channeling, is operated through the mechanical tuning unit module, the control of which is maintained at Radio Set Control C-1607/ARC-52.

The a-c power unit (RT-332/ARC-52 only, fig. 16-22 (B)) receives voltages from the 3-phase, 115-volt a-c and the 27.5-volt d-c power sources and distributes them to the required modules. The a-c voltage is applied to the rectifier unit, and the d-c voltage is applied to the relay unit and the mechanical tuning unit. In addition, the a-c power unit supplies a rectified output of 425 volts d.c. to the relay unit, and filament supplies of 6.3 volts a.c. and 26.5 volts a.c. to the appropriate filament distribution points.

The rectifier unit (RT-332/ARC-52 only) receives 115 volts a.c. from the a-c power unit and provides plate and bias voltages of +130 volts, +225 volts, and -15 volts d.c. The relay unit controls the transition between the transmit and receive function which, in turn, are controlled by the microphone press-to-talk switch. It provides three power switching functions:

1. Disable, wherein channeling will cause the AN/ARC-52 to revert to the receive function and any received audio signal is grounded.
2. Guard, wherein plate voltage is controlled for guard receiver operation.
3. Tone, wherein a continuous homing signal, 1000-Hz tone, is transmitted.

The relay unit provides selective switching of positive d-c voltages of 27.5, 130, 225, and 425 volts.

The dynamotor power supply unit (RT-424/ARC-52X only) receives 27.5 volts d.c. from an external power source and distributes this

13655

voltage to internal circuits. The same voltage also excites a dynamotor to produce d-c voltages of +425 and +130. From these voltages, additional d-c voltages of +225 (regulated) and -15 are developed. All d-c output voltages from the dynamotor power supply unit are applied, either directly or through the relay unit, to the plate, screen, and grid circuits in the receiver-transmitter.

A mechanical tuning unit controls the frequency selection of the equipment and, in turn, is remotely controlled from Radio Set Control C-1607/ARC-52. It operates in a manner similar to that on the AN/ARC-88.

TRANSCEIVER ALINEMENT AND TRACKING

A transceiver is a self-contained transmitter and receiver which share common circuits. The transmitter and receiver both operate on the same frequency, and the microphone switch determines when there is an output from the transmitter. In the absence of transmission, the receiver is sensitive to incoming signals.

Some of the common circuits are the antenna, master oscillator, and RF and AF amplifiers. Advantages of these common circuits are the overall reduction of the size and weight, and the lower power demand on the aircraft system.

Since there are circuits common to both the transmitter and the receiver, alinement and tracking are unique problems of the transceiver. Alinement is the adjustment of circuits to specific frequencies, and tracking is maintaining a constant frequency relationship between two or more circuits.

In order to aline and track common circuits in a transceiver, it is necessary to refer to the Service Instructions Manual for the particular equipment being used. This is because the circuits common to both the transmitter and receiver will vary from equipment to equipment; for example, between the ARC-44, ARC-52, ARC-88, and the ARC-94.

INTERCOMMUNICATION SYSTEMS

All aircraft intercommunication systems perform essentially the same basic functions. They deliver audio to one or more selected stations on board the aircraft to permit crewmembers to speak to each other. They also provide control of the communication facilities so that various members of the crew may receive incoming radio messages or initiate messages with the aircraft transmitters. It is also often necessary that the intercommunication system contain facilities for operating recording equipment so that permanent records may be made of the various receptions and transmissions occurring during flight.

It is not possible in the limits of the present discussion to describe all types of intercommunication systems installed in naval aircraft. A few examples are given which show characteristics common to most installations, while at the same time presenting characteristics which represent the newer developments in this type of equipment.

INTERCOMMUNICATION SET AN/AIC-14

The AN/AIC-14 ICS is an airborne internal communication system which integrates and coordinates all the audio facilities of the communication and other electronic equipment. The overall design is based on modular construction to provide a very high degree of versatility and reliability. Easily replaceable plug-in transistorized amplifier modules insure reliability under severe environmental conditions. A variety of individual component parts and subassemblies are available for use with and within the system, permitting adaptation of the basic system for use in many different types of installations having various audio requirements. Thus the basic system and its numerous variations provide for almost trouble-free service over prolonged operating periods.

The maximum capability for AIC-14 interphone installations in a single system permits operation of any combination of up to 30 individual stations without readjustment of the interphone volume control. Under maximum usage the overall output level from the control unit does not vary by more than 3 db. All signal inputs are isolated from each other by at least 50 db, thus minimizing the effect of a single station on the operation of the overall system.

r2ac113656

ASSIGNMENT:

On an 8" x 11" buff drawing paper, draw in ink a $\frac{1}{2}$-inch border all around. Through the middle of the paper draw a line across the sheet. Draw the lines shown below, spacing them $\frac{1}{2}$ inch apart. When completed, clean pen thoroughly and store.

1363

In addition to the interphone stations which are normally manned during aircraft operations, auxiliary stations may be provided for use by ground personnel during maintanance, inspection, or servicing of the aircraft. Any combination of audio inputs (up to a total of 30) may be monitored without requiring adjustment of the volume control. Through operation of control switches, up to 11 outputs may be controlled.

The selection and monitoring of interphone and radio receiver signals, as well as the selection of transmitters to be keyed, is accomplished through selector switches and controls located on the front panels of the units to be controlled. The modes of operation (normal or auxiliary) and the energizing or deenergizing of interphone station microphones are controlled by operating appropriate switches on the front panel of the interphone control. The interphone control also permits the use of external keying switches.

To illustrate the flexibility and versatility of the AN/AIC-14 system, some of the various types of components and accessories are described briefly. The discussion is limited to the important features and peculiar applications of each item discussed. The list, although quite extensive, is far from a complete listing of items used in conjunction with the AN/AIC-14 Intercommunication Set.

Control Units

Control, Interphone C-2645A/(or C-2645B)/AIC-14 is the master control unit for the system, and is located at all manned interphone stations. Two transistorized plug-in amplifier modules (one isolation and one interphone) are included in each unit. The isolation amplifier provides the amplification and isolation necessary for all incoming audio (interphone and radio receiver). The interphone amplifier provides the amplification and isolation necessary for all outgoing audio (from the station's microphone). Each amplifier is capable of delivering a nominal output power of 300 milliwatts to the stations' earphones or to the interphone line.

The control unit also provides an alternate mode of operation for either or both amplifiers. If one amplifier becomes inoperative, its functions may be shifted to the other; if both the amplifiers become inoperative, they may be bypassed by switching to the EMERG position. In the emergency mode, incoming signals are supplied directly to the headset and outgoing signals are fed directly to the transmitter; no interphone communication is possible.

In almost all aircraft, additional control units are used to extend and expand the capacity of the ICS. A few such auxiliary control units are discussed briefly in the following paragraphs.

The C-2642/ or C-2642A/AIC-14 provides a means for selecting transmitter or interphone operation, interphone disconnect, and volume adjustment of incoming radio receiver signals. Any one of up to 11 transmitters can be selected.

The C-2643/AIC-14 is a selector panel for radio receivers and transmitters, permitting selection of any combination of two transmitters and four receivers. It incorporates isolation networks for all incoming signals.

The C-2644/AIC-14 incorporates facilities for selecting transmit or receive operation, a volume control for mixed radio receiver signals, and isolation for all incoming signals.

The C-2646/AIC-14 is an auxiliary control used primarily by maintenance personnel. It is located at auxiliary stations not normally manned during flight. It uses the common audio line for both incoming and outgoing interphone signals, and permits communication with any station which is connected to the common audio line.

The control contains a single amplifier. Incoming audio signals are isolated and amplified; in this case the amplifier acts as an isolation amplifier. When a push-to-talk circuit is energized, the microphone input is amplified and fed to the common line; the amplifier then switches to interphone operation.

The microphone and headset jacks can be used only with a 600-ohm headset and a carbon microphone with a nominal impedance of 100 ohms. When a dynamic microphone and low impedance headset are used, signal preamplification and transformer matching are required. This may be conveniently accomplished with the use of associated accessory cordsets discussed later in this chapter.

The mounting plate MT-2075/AIC-14 is used in conjunction with the C-2646. It includes a quick-dismounting feature provided by four slide fasteners which are secured by lockwire.

13657

The C-2647/ or C-2647A/AIC-14 provides facilities for increasing the number of either receivers or interphone stations. It provides isolation for all signals. The function as interphone station selector or as receiver selector is determined by the position of an internal plug-in unit. This function is established at the time of installation, and is not normally changed thereafter.

When used as a receiver selector, any one or any combination of 12 receivers may be selected and isolated. When used as an interphone station selector, the unit selects and isolates any one or any combination of 12 signals. An alternate provision enables position 12 to be used either to select a specific station or as an "all-call" for up to 11 stations.

The C-2648/ or C-2648A/AIC-14 control permits selection of six additional receivers or interphone stations. In other respects it is similar to the C-2647.

Interconnection Box J-1013/AIC

This accessory enables the AN/AIC-14 to operate with either carbon or dynamic microphones and either high or low impedance headsets. The unit contains a 60-db transistorized preamplifier and two impedance matching transformers. The preamplifier and transformers may or may not be used, depending on the position of the connecting links in the box. A table illustrating the link settings for various types of microphones and headsets is located on the inside of the cover plate.

Microphones

A carbon microphone may be connected directly into the AN/AIC-14 Intercommunication Set, or it may be connected through a J-1013 interconnection box. If the J-1013 is used, the links must be set so as to bypass the microphone preamplifier. Dynamic microphones, if used, must be connected through the J-1013. The links must be set so that the 60-db gain of the microphone preamplifier is used.

The RS-38D-2 is a hand-held, high output (0.25-volt, rms), noise-canceling carbon microphone. Its termination (plug PJ-068) mates with the MIKE jack on the interphone control C-2646 or on any installation which accommodates conventional carbon microphones.

The M-3A/A is a high output (0.25-volt, rms), boom-mounted, noise-canceling carbon microphone. Its termination (PJ-292) is a two-prong plug which mates with the receptacle on the H-173/AIC headset and the CX-1301/AR cordset.

The ANB-M-C1 is a high output (0.25-volt, rms) carbon microphone normally used in oxygen masks. It terminates in the PJ-292 plug.

The M-92/U is a hand-held, noise-canceling, dynamic microphone with a built-in transistorized amplifier. In appearance and characteristics it is the equivalent of the RS-38D-2 carbon microphone, and may be used interchangeably with it. If a J-1013 is used, the link settings should bypass the preamplifier.

The M-96/A is a boom-mounted, noise-canceling, dynamic microphone similar in appearance to the M-3A/A carbon microphone and terminated in the same type (PJ-292) plug. In use, however, the two are not interchangeable. The M-96/A has a nominal output impedance of 7 ohms, and delivers an output voltage of 300 to 500 microvolts. The J-1013 must be used, and the microphone preamplifier and the appropriate impedance matching transformer must be connected by the changeable links.

The M-94/A is the dynamic microphone used in oxygen masks. In appearance it resembles the AMB–M-C1, but the two are not operationally interchangeable. In electrical characteristics and service limitations, the M-94/A resembles the M-96/A.

Earphones and Headsets

Several types of earphones and headsets are used with the AN/AIC-14 system. In actual practice the headsets may be so constructed that the earphones are either used separately (split-phone) or connected in parallel. They may have either a low or a high impedance.

Earphones H-87B/U are the dynamic type commonly used in helmets and headsets. The earphones have an impedance of 7 ohms as compared to the 600-ohm impedance of the ICS. The phones may be connected to a 25020 cordset which is terminated in a short plug. In this arrangement, an impedance matching transformer in the plug permits the H-87B/U to be inserted directly into the ICS control box. If connected through the J-1013, the links should bypass the impedance transformers.

13658

By using the cordset CX-4832 the earphones are connected in parallel, offering a 7-ohm impedance. This combination requires use of the J-1013 and its impedance matching transformers.

The H-173/AIC headset is a lightweight unit which is designed for maximum wearing comfort. It contains the H-87B/U earphones and incorporates provisions for mounting boom microphones. The earpieces eliminate most of the surrounding noise. A quick-disconnect feature provides safety and ease of handling.

The H-3/ARR-3 is a dynamic headset with built-in impedance matching transformer, which adapts the 7-ohm phones to the 600-ohm system. This allows the headset to be directly inserted into the ICS. If connected through a J-1013, the impedance transformer must be bypassed.

Cordsets

Many types of cordsets are used with the AN/AIC-14. These cordsets are used for connecting the various types of microphones, headsets, and connection boxes within the system. Some include amplifiers and/or impedance transformers; others do not. The following paragraphs present a brief discussion of several of these cordsets.

The CX-1301/AR is a coiled cordset terminated on one end with a Junction Box J-193/AR and on the other end with a U61-U receptacle. The cordset is normally used with carbon microphones and high impedance headsets. If incompatible accessories are used, the J-193/AR is removed from its mounting and the CX-1301/AR is replaced by a J-1013. The mounting holes of both connecting boxes coincide.

The CX-4620/AR is a 75-foot, 5-conductor cable with an in-the-line switch containing a preamplifier, impedance transformer, and microphone keying switch. One end is terminated in a connector which mates with the J-1013 input connector. The other end mates with the H-173/AIC headset or a hardhat. This cordset may be used only with a dynamic microphone and a low impedance headset. However, the adjustable links in the J-1013 must be set to accommodate a carbon microphone and high impedance headset combination.

The CX-4621/AR is a 6-foot, 5-conductor, coiled cordset with terminations identical to those of the CX-4620/AR. Since it contains no preamplifier or impedance matching transformers, it may be used with either type headset and microphone. However, the links in the J-1013 must be connected accordingly.

The CX-4623/AR is a 9-foot, 5-conductor, coiled cordset. It includes an in-the-line switch similar to that in the CX-4620/AR, and is terminated in the same type connectors. It may be used only with a dynamic microphone and low impedance headset, but the J-1013 links must be set for the carbon microphone and high impedance headset combination.

The CX-4832/AR cordset is used to connect the earpieces of the H-87B/U in parallel, thus providing a low impedance output.

INTERCOMMUNICATION SET AN/AIC-15

The AN/AIC-15 system, marks a milestone in adaptation of transistor circuits to airborne applications in a form suitable for manufacture on a production basis. The total equipment consists of six types of major components; four types of station control boxes, a recorder control, and an interconnecting box.

Each of the control boxes with the exception of the recorder unit contains one microphone amplifier and one receiver amplifier. The type of box installed at a particular station of the aircraft is determined by the communication functions to be performed at that station. All boxes provide essentially the same intercom and receiver facilities. The system is not restricted to use with any specific radio receiver, recorder, or transmitter, but may be used with many different radio communication equipments.

System Operation

The major components of the AIC-15 are connected as shown in the block diagram in figure 16-23. The master unit (C-1908) contains controls for the complete set of radio and intercom facilities. The flight crew control (C-1910) provides the means for controlling two radio transmitters and for listening to two radio receivers. The recorder control (C-1912)

13659

AT.300

Figure 16-23.–AN/AIC-15, system block diagram.

serves to route any of the signals present to a tape recorder so that it is possible to preserve the audio information exchanged during operation.

The central unit of the system, Interconnecting Box, J-758, connects incoming receiver signals to the various stations and also connects the control boxes to the aircraft transmitters for control of the latter during transmission. The interconnecting box can also be used as an additional control station since it contains jacks for a microphone and a headset.

Each of the station control boxes contains a microphone amplifier and a receiver amplifier and is therefore independent of any outside aid except d-c power. Thus, external cables are not required as would be the case with external amplifiers; and smaller wires are used due to lower power requirements. As a result, approximately 60 pounds of cable weight are eliminated in comparison with electron-tube counterparts of the system. An additional advantage of this compact method of amplifier packaging is increased flexibility, in that the number of control units can be decreased or increased without causing any deterioration in the performance of the system.

Because of the relatively low power consumption of the AIC-15, the system contains no on-off switch as such. The equipment is powered from a 28-volt, d-c supply and remains in the ON condition as long as the aircraft power system is in operation.

All audio switches are semiconductor devices. By placing an appropriate d-c bias on a particular interphone line, audio on that line can be routed into the control boxes attached to it. The audio switch for each interphone line is a germanium diode which acts as a short circuit to audio when a forward d-c bias is

13060

established. Conversely, the diode acts as an open circuit when back biased, thereby disconnecting the interphone line from the associated control boxes.

Under certain conditions it is necessary to use the intercom facilities while monitoring the output of the aircraft radio receivers. It is then desirable to reduce the volume of the receiver audio without eliminating it entirely. To accomplish this, the nonlinear impedance feature of a transistor is used to reduce the receiver audio that is present with the interphone signal at the receiver amplifier.

The radio volume is lowered by means of a d-c bias applied to the volume-reduction transistor, thereby changing the latter from a nonconductive to a conducting state. This, in turn, changes the impedance of the radio receiver audio input network in such a manner as to reduce the applied audio. As a result, the volume of the output from any radio receiver selected at a given control unit is reduced approximately 10 decibels with respect to the interphone level.

Interphone Circuits

A single interphone line is employed with each type of control station in the AIC-15 system. For example, the pilot, copilot, and radio operator are on a single interphone line and the remaining crew stations are on another. There is also a separate line to which all control stations are connected, which makes it possible to talk from any control box to all other stations in the system.

An emergency, or override, feature is provided by a separate line under control of the pilot, copilot, or radio operator. The emergency line can be switched on quickly and communication established with all crewmembers on the aircraft.

In addition to the interphone facilities, the AIC-15 circuits provide the means for listening to any combination of 9 radio receivers and for controlling the operation of any of 9 radio transmitters. The total number of stations may be as high as 13, a relatively large capability which is achieved with comparatively small requirements of space, weight, and power. The system is designed to operate on 10 watts of 28-volt, d-c power per control unit.

Transistor Amplifiers

As stated above, all the station control boxes (with the exception of the recorder unit) contain two compactly packaged transistor amplifiers—one for microphone amplification and the other for receiver audio amplification. Electrically, the two amplifiers are almost identical. The input circuit of the microphone amplifier is designed to work with a carbon microphone, whereas the input of the receiver amplifier is a conventional RC coupled, 600-ohms circuit. The output circuit in both is transformer coupled, consisting of an 800-ohm output from the microphone unit and a 600-ohm output from the receiver amplifier. Both are three-stage amplifiers with push-pull output and overall negative feedback. The receiver amplifier is illustrated in block diagram form in figure 16-24.

Both the microphone and receiver amplifiers employ silicon transistors. The input stage of the receiver unit is a type 904. The 951 transistor driver is transformer coupled to two 951 transistors which serve as a push-pull output stage. The first two stages are grounded emitter circuits with collector-to-base negative feedback and emitter resistance temperature stabilization. The output stage is a grounded base circuit biased for class B operation. An overall negative feedback loop of about 20 decibels is used to further stabilize the circuit operation.

The overall dimensions of each AIC-15 amplifier are 2.44 by 1.72 by 1.00 inches. The maximum power gain is approximately 35 decibels with a gain control provided to reduce the output signal to zero. The amplifiers are capable of an output of 300 milliwatts at less than 10 percent distortion and an output of 150 milliwats at less than 5 percent distortion. The frequency response is flat within ±2 decibels

AT.301

Figure 16-24.—Block diagram of the transistorized receiver amplifier.

13561

from 400 to 6,000 hertz. Satisfactory operation is maintained over the input B-plus voltage range of 22 to 30 volts d.c. About 80 milliamperes of current are required at the 28-volt B-plus level.

The amplifiers are potted to reduce vibration damage. For maintenance, the entire unit is replaced and no attempt is made to repair any component within the amplifiers. The weight of each amplifier is approximately 5 ounces, a very favorable figure when compared with a weight of 13 to 15 pounds in comparable units of older systems. Also with lower power requirements, an approximate reduction in load of 20 percent is realized.

Intercommunication Set AN/AIC-15 is of considerable importance for the Aviation Electronics Technician since it is one of the first completely transistorized electronic systems which have demonstrated capability of meeting all military requirements of its class and which has definite advantages when compared with hitherto standard designs. Among these are a relatively larger number of facilities controlled, less size and weight, lower power requirements, and greater reliability and flexibility as compared to its vacuum tube counterparts. The design specifications require at least 2,000 hours of satisfactory service without removal for bench servicing, a feature of essential importance for maintenance personnel. From the standpoint of operation, one of the outstanding features of the system is its clearness of transmission.

13062

CHAPTER 17

AIRBORNE NAVIGATION EQUIPMENT

Airborne navigation equipment is a term embracing many systems and instruments. The technician is required to maintain and, in some instances, to operate various equipments. This chapter includes a discussion of the major navigational systems in present use, with reference to some typical equipments. These systems include electronic altimeters, radio range and related facilities, loran, radio direction finders, Doppler radar systems, and inertial navigation equipment.

ELECTRONIC ALTIMETERS

Electronic altimeters may be classified as radio or radar altimeters. They may operate on frequency modulation principles, or they may be pulsed. Electronic altimeters are frequently referred to as absolute altimeters, because they are used to measure height above the terrain rather than with respect to sea level.

This chapter contains a brief discussion of two of the later and more accurate altimeters in present use in the fleet.

ELECTRONIC ALTIMETER AN/APN-120

The Altimeter Set, Electronic, AN/APN-120 furnishes accurate radar altitude (above terrain) indications over all types of terrain and under any weather conditions. It operates on two ranges. The low range measures altitude up to 3,000 feet; the high range measures altitude from 500 feet to the maximum altitude of the aircraft. It is installed in the RA5C model aircraft and is an integral part of the weapons system. In addition to furnishing accurate altitude data for the pilot, the system also supplies data for correcting the barometric altitude calculated by the air data system. The final corrected barometric altitude information is used by the bomb directing set to compute weapon delivery patterns.

Characteristics

The altimeter system consists of a hybrid radar system. The low altitude subsystem consists of an amplitude-modulated, frequency-modulated, continuous-wave (AM-FM-CW) C-band radar set; the high altitude subsystem is of the pulsed type. Provisions are made for a low altitude warning light, which actuates at 400 feet altitude above terrain, and an indicator of signal reliability.

System functional loops represent the complete paths of signal flow within the system, subsystems, and circuits. These loops are not limited by their packaging or "black box" location.

Theory of Operation

For purposes of this discussion, the theory of operation for the AN/APN-120 is divided into a brief discussion of the functional loops. For detailed information regarding this equipment, refer to the applicable technical manuals. Figure 17-1 is a simplified block diagram of the altimeter, and should be referred to frequently in connection with this discussion.

LOW ALTITUDE MEASUREMENT LOOP.– The low altitude system transmits and receives an RF carrier in the C band of radar frequencies. The carrier is frequency modulated by 25 kHz, which is itself amplitude modulated by a 400 hertz voltage. (The 25 kHz modulation is required to develop frequencies representative of altitude.

13663

13663

AT.303

Figure 17-1.–Altimeter Set, Electronic, AN/APN-120, simplified block diagram.

13664

The 400 Hz modulation is used to develop an error voltage when a difference exists between the altitude indicated by the returning RF energy and altitude indicated on the altitude readout. When an error voltage is developed, the servoloop corrects the indicator to agree with the radar return.)

In the transmitting portion of the low altitude loop, a 25 kHz signal is generated by an oscillator and modulated by a 400 Hz voltage from the aircraft supply. This complex signal is routed to the repeller of the klystron, thereby varying the klystron frequency of oscillation. The modulated RF is fed through a directional coupler to the low altitude transmitter antenna. A mode-centering circuit maintains the center frequency of the klystron at the center of its power mode.

The low altitude receiving antenna receives the signal reflected from the ground and feeds it to a frequency mixer. A sample of the transmitted signal is also routed (through a frequency translator) to the mixer. The input frequency of the translator is shifted so that the output is 262.5 kHz above the input frequency. The mixer output is a 262.5 kHz signal with sidebands corresponding to the frequency modulation on the received signal. Since the FM component of the received signal is 25 kHz, sidebands occur at multiples of 25 kHz away from the center frequency. This composite signal is then fed to the 212.5 kHz IF amplifier.

The maximum gain of the IF amplifier is governed by a gain control voltage from the servoloop, so that the gain is a function of altitude. The output of the amplifier programer unit is detected and filtered to produce an AM component and a d-c component. The d-c component provides the automatic gain control voltage and an indication of reliability. The AM component is compared with the aircraft 400 Hz reference to produce a correction signal for the height indicator.

HIGH ALTITUDE MEASUREMENT LOOP.–The transmitting portion of the high altitude system begins at the range computer. This stage initiates a trigger pulse at a stable repetition rate. The trigger pulse is used in the radar modulator to time and trigger the pulse forming circuits which pulse modulate the transmitter. The modulator also supplies a negative blanking voltage, synchronized by the same trigger, to the electronic gate.

The pulse cavity transmitter is caused to resonate by the modulator pulse, and supplies an RF pulse at approximately 4225 MHz to the antenna arrays. When the transmitted pulse is reflected from the terrain, a portion of the reflected wave is intercepted by the receiving antennas and becomes the received signal.

The received signal is fed into the high altitude frequency mixer. The CW cavity oscillator generates an a-c voltage at 4165 MHz for use as the local oscillator signal. In the mixer, the received signal (4225 MHz) beats with the local oscillator signal (4165 MHz) to produce an IF signal of 60 MHz.

In the IF amplifier, the gain is regulated by an AGC voltage. During transmit time, gain is reduced to almost zero by a blanking pulse from the electronic gate. This blanking pulse prevents self-triggering by the system's own transmitter. After amplification, the IF signal is detected to produce a video pulse.

The video pulse is gated, timed, and shaped in the programer unit to produce the altitude indication for comparison with the altitude reading on the indicator. Any difference between these values produces an error signal for the servoloop, which then corrects the reading of the instrument.

PROGRAMER.–The programer is common to both the low altitude and the high altitude systems. The programer is made up of circuits, which are partly interdependent in their operation, and performs the following functions which are not discussed in detail:

1. To process the d-c error signals (for low and high altitude range) to provide the required driving signal voltage for the respective servomotor.

2. To perform the required switching functions according to operational mode selection.

3. To provide automatic turn-on of the low altitude system when the altitude is less than 4,000 feet.

4. To provide time-sharing pulses which cause the two systems to alternate their "on" time whenever both systems are operating and the aircraft is at an altitude between 0 and 4,000 feet.

13665

RADAR ALTIMETER AN/APN-141(V)

Electronic Altimeter Set AN/APN-141(V) is a C-band, pulsed, rangetracking radar that locks onto the leading edge of the echo pulse. It provides a continuous, highly accurate indication of absolute altitude from 10 to 5,000 feet above water or terrain. The accuracy and the reliability make possible extremely low altitude instrument flight missions in familiar or level territory. It also increases the safety of moderately low-level instrument flight missions into territory where the barometric pressure and terrain elevation data are unreliable or unknown.

The equipment consists of the radar transmitter-receiver unit, an RF switching unit, a height indicator, and two antennas.

Characteristics

Altitude information is continuously displayed, in feet of absolute altitude, on a panel-mounted indicator. This information is developed by radiating pulses of microwave energy downward and by monitoring the time required for the return of each pulse as an echo. Monitoring of pulse transit time is accomplished by means of a leading-edge electronic tracking loop which, in effect, locks onto the range of the water or terrain, and follows variations of clearance resulting from aircraft maneuvers or terrain elevation.

Leading-edge tracking provides for an indication of the nearest terrain under the aircraft, and not necessarily the terrain directly under it. Thus, the altimeter set will track a mountainside or a cliff ahead or to the side of the aircraft if this terrain is closer than the ground directly below the aircraft. This feature provides essential warning of rapidly decreasing absolute altitude on low-level missions.

The system has two altitude modes of operation–one for low altitudes and one for high altitudes. At low altitudes (0 to 195 feet ascending and 165 to 0 feet descending), a very narrow, low-powered transmitted pulse is utilized to obtain maximum range resolution. The low altitude pulse is also programed in width to provide the proper strength of the ground return signal with altitude variation. At altitudes above the ascending and descending upper altitude limits, a wider high-power transmitted pulse is utilized to obtain sufficient ground return energy for tracking.

The altimeter system also has two ranging modes of operation–the search mode and the tracking mode. In the search mode, the system successively examines increments of range with each cycle of operation until the complete altitude range is searched for a ground return signal. When the altitude range is found, the system switches over to the tracking mode of operation. In the tracking mode, the system locks onto and tracks the leading edges of the ground return pulses and presents continuous altitude information.

Altitude information is obtained by measuring the time intervals from the instant that each pulse of RF energy leaves the transmitter until the leading edge of the ground return signal is detected in the receiver. The system converts this time interval information to a d-c range voltage which is offset in amplitude to form an altitude d-c voltage analog. This analog is fed to the height indicator which indicates altitude in feet proportional to the amplitude of the d-c voltage.

Theory of Operation

For the following general discussion of the theory of operation for Electronic Altimeter Set AN/APN-141(V), refer to figure 17-2. For more detailed information, refer to the applicable technical manuals.

TRANSMISSION.–Clock pulse 1 functions as the basic system timing trigger. This pulse is generated at a 3 kHz rate in the time comparator and is fed to the modulator where it triggers each transmission and cycle of operation. The modulator pulses the transmitter cavity and produces a crystal switch drive signal for gating the narrow RF pulse transmitted during low altitude operation. This gating is accomplished in the RF switching unit. The modulator also produces a range-timing ramp trigger for use in the time comparator during low altitude operation. The modulation pulse drives the transmitter cavity into oscillation, and the transmitter cavity energy is applied to the RF switching unit. A detected sample of the energy is taken from the cavity as a range-timing ramp trigger for use in the time comparator during high altitude operation.

UNIT V - TRACING

How To Sharpen a Pen — Lesson 2

OBJECTIVE: To learn the art of sharpening a pen.

RELATED INFORMATION:

As previously stated, beginning draftsmen should possess some competence in the art of inking, for they most assuredly will be called upon to use this technique at one time or another throughout their careers.

In order to draw well in ink, the pen must be kept sharp. This lesson will be devoted to teaching you the art of sharpening a pen.

When preparing to sharpen a pen, an oil stone usually affords best results. The nibs of the pen must first be brought to the correct shape, as shown in Fig. 1. When the nibs are touching, draw the pen back and forth on the stone, starting the stroke with the handle at 30° or less with the stone. The nibs will then be brought to exactly the same shape and length, leaving them very dull. At this point open them slightly and sharpen each blade in turn on the outside only, until the bright spot on the end has just disappeared.

FIG. 1

Now, as in Fig. 2, hold the pen at a small angle with the stone and rub it back and forth with a slight rocking motion to conform to the shape of the blade.

FIG. 2

To believe that you will achieve good results initially is foolhardy. Practice and more practice, alone, will enable you to sharpen a pen properly.

QUESTIONS:

1. Why bother to sharpen a pen?
2. Which part of the pen is sharpened?
3. Describe the correct shape of the nibs after sharpening?
4. Why should you learn to ink drawings?

AT.304

Figure 17-2.–Altimeter AN/APN-141(V), block diagram.

13667

The RF switching unit is controlled by the d-c level of the range voltage input from the receiver, and performs two basic functions: gating of the peak power and width of the transmitted pulse, and switching of the potential on the altitude mode control line. During high altitude operation, the unit routes the full 1-kilowatt output of the transmitter cavity directly to the transmitter antenna and grounds the altitude mode control line. During low altitude operation, the unit attenuates, narrows, and programs the width of the cavity output pulse before application to the antenna. It also places a positive voltage on the altitude mode control line. The potential on the altitude mode control line enables or inhibits circuits in the modulator, time comparator, and receiver to provide the proper gating and timing in these three modules for each altitude mode.

RECEPTION.–The receiver antenna senses ground return signals and applies these pulses of RF energy to the receiver cavity. The receiver cavity is a superregenerative detector that generates an output only when pulsed by a positive grid signal. This signal is supplied by the receiver pulse generator in the time comparator. The cavity generates an output each time the receiver pulse is applied, but this output is of greater peak amplitude when ground return energy is present in the cavity than when this energy is absent.

The receiver pulse is generated twice during each operational cycle: First, for detecting the possible presence of ground return energy in the cavity, and later, when no ground return energy can be present for sampling the noise level in the cavity. Either type of cavity output is detected, and resulting high or low amplitude video signal is fed to the receiver. Simultaneous with cavity grid pulsation, the receiver pulse activates the receiver for two brief intervals in the operational cycle.

During the first interval, the receiver examines the video signal for the possible presence of a ground return signal. If the signal is absent, the receiver maintains the system in the search mode of operation. If the signal is present, the receiver switches the system over to the tracking mode.

During the second interval, the receiver samples the noise level in the cavity and utilizes the low amplitude video input to regulate the width of the receiver pulse for the automatic stabilization of receiver gain.

The receiver also utilizes its range voltage output to regulate the width of the receiver pulse for the adjustment of receiver sensitivity to ground return pulses with variations in altitude. Clock pulse 2, from the time comparator, triggers a circuit in the receiver that generates the receiver pulse width control signal.

SEARCH MODE OPERATION.–Figure 17-3 shows the idealized basic waveforms and time relationships involved in altitude acquisition and tracking. The (A) set of waveforms is common to both modes, and shows the basic timing and transmission references. The (B) set of waveforms applies to the search mode of operation, and the (C) and (D) sets apply to the tracking mode. The 3 kHz pulse repetition frequency of clock pulse 1 establishes a basic system period of approximately 333 microseconds for both the high and low altitude modes of operation. The signals and events required for altitude acquisition and tracking occur during the first 10 microseconds of this period over the interval of the range-timing ramp. (Since a radar time of 2 microseconds is approximately equivalent to an altitude of 1,000 feet, this first 10-microsecond timing interval corresponds to the 5,000 foot maximum altitude capability of the system.)

In the search mode, the range voltage from the receiver is a freerunning sweep of 2.5-second duration. The range-timing ramp and the range voltage sweep are both fed to a voltage comparator in the time comparator. When voltage coincidence of the ramp and range sweep occurs, the voltage comparator triggers the receiver pulse. The receiver pulse biases the receiver cavity into conduction and triggers a gate in the receiver that momentarily enables amplification and switching circuits to examine an increment of altitude. With no ground return signal present, the receiver cavity generates a small video signal that results from the buildup of the noise level in the conducting cavity.

The equal intervals in the first train of ground return signals shown in figure 17-3(B) represent the pulses present in the receiver cavity at a constant altitude. Over successive cycles of operation, the receiver pulse approaches the ground return pulse in time because of the successive delays in ramp and

13668

range sweep voltage coincidence. Throughout a complete 2.5 second range voltage sweep, the receiver pulse is generated approximately 7,500 times, and the altitude is effectively probed in increments of 1 foot. When the receiver pulse reaches the ground return signal in time, the video output from the receiver cavity builds up considerably above the previous levels attained by noise buildup, and switches the receiver from the search to the tracking mode of operation. The video input is then used as a range voltage amplitude control, resulting in the leveling of the range voltage at an amplitude equivalent to the time interval between the transmitted and ground return pulses.

TRACKING MODE OPERATION.–When switched over to the tracking mode, the receiver and the time comparator operate together to time the occurrence of the receiver pulse with a point on the slope of the leading edge of the ground return pulse. (See fig. 17-3(C).) With a constant altitude and a consequent steady range voltage, as well as fixed ground return period, this synchronism is merely coincidental. The automatically controlled synchronism required for following altitude changes is provided by a tracking servoloop consisting of the same basic components used in the search mode (switched to the tracking mode of operation).

In the tracking mode, the range voltage still tends to rise, but with a much shallower slope than in the search mode. The tracking servoloop utilizes both this slight tendency of the range voltage to rise if uncontrolled and the sensitivity and power buildup characteristics of the receiver cavity as a governing mechanism for locking onto and tracking altitude changes. At the leading edge of the receiver pulse, cavity sensitivity rises sharply to a maximum value and then falls off exponentially to a zero value near the trailing edge of the grid pulse.

The center set of curves in figure 17-3(D) shows the operation of this governing mechanism at a constant altitude. Here the leading edge of the grid pulse is timed to coincide with a nominal power level on the leading edge of the ground return pulse. The point of maximum cavity sensitivity coincides with this nominal RF power level. The buildup of cavity output power, because of the exponential curve of the sensitivity characteristic, is linear. Averaged over succeeding cycles of operation, the buildup is just sufficient to keep the range voltage at a constant level, maintaining a constant period of ramp and range voltage coincidence and a consequent fixed grid-pulse spacing. The results are a steady d-c voltage analog to the height indicator and a constant altitude indication.

The lower set of waveforms in figure 17-3 (C) shows how the system tracks a ground return pulse train whose period shortens successively with decreasing altitude. The second receiver pulse, whose spacing from the first pulse is governed by the previous coincidence of ramp and range voltage, occurs slightly delayed with respect to the ground return pulse. Receiver cavity buildup of video output power increases and drives down the range voltage and altitude analog. This causes range and ramp voltage coincidence to occur earlier and the receiver pulse to follow the leading edge of the ground return pulse.

The left set of curves in figure 17-3(D) shows the operation of the tracking servoloop with a decreasing altitude (or with any tendency of the grid-pulse spacing to drive toward a longer period than that required for tracking). The ground return pulse arrives slightly earlier than for a constant altitude, and the leading edge of the grid pulse coincides with a higher power level on the leading edge of the ground return pulse. The consequent higher peak buildup of cavity output power, averaged over a number of operational cycles, drives the range voltage and altitude analog down.

The right set of curves in figure 17-3(D) shows the operation with increasing altitude (or with any tendency of the grid-pulse spacing to drift toward a shorter period than that required for tracking.) The ground return pulse arrives slightly later than for a constant altitude, and the leading edge of the grid pulse coincides with a lower power level. The consequent lower peak buildup of cavity output power, averaged over a number of cycles, allows the range voltage and altitude analog to rise. Thus, the time coincidence of the ramp and range voltage, controlled by the amount of peak video power developed from the initial level of RF signal power at the leading edge of the grid pulse, adjusts the spacing of the receiver pulse automatically to track the leading edge of the ground return pulse. The resulting altitude analog, which follows the range voltage, thus tracks a balance of two op-

posing forces–the tendency of the range voltage to rise as the output of a shallow sweep generator, and the force of the average video power that drives the outputs of the sweep generator down.

ALTITUDE INDICATION.–The height indicator is a servo-driven device that positions the pointer at an altitude proportional to the d-c voltage analog from the receiver. In addition, the indicator provides two alerting functions. An OFF flag comes into view in the center of the indicator dial whenever the altimeter is not tracking a ground return signal. A low altitude warning system, which can be set to any altitude from 0 to 5,000 feet, causes a red warning light (in some aircraft installations) on the aircraft instrument panel to illuminate when the aircraft descends below the preset altitude.

BENCH TEST AND CALIBRATION

Most of the later electronic altimeters require the use of a specific test set that is designed only for that particular model altimeter. Some altimeters, such as Electronic Altimeter Set AN/APN-120, are a part of a larger navigation system and have the advantage of being checked for operation and calibration while in stalled in the aircraft by the use of the aircraft system computer.

Other altimeter types can only be checked in the aircraft by the use of a test set commonly known as a "GO-NO GO checker." This test set is normally a fixed delay line. Test sets of this type are discussed under line test equipment in chapter 8 of this manual.

The Integrated Weapons Shop Test Set AN/USM-124 is specifically designed for shop bench test and for calibration of the AN/APN-120 altimeter. By using the Line Test Set AN/USM-125, a programed tape, and the aircraft computer, faulty units can be located very readily during line maintenance.

The AN/APN-141(V) altimeter also has its own bench test set, Altimeter Test Bench Set TS-1979A/APN-141(V). Any time that maintenance is to be performed on either the transmitter-receiver or the RF switching unit, both units must be calibrated as a matched pair with the bench test set.

Earlier altimeters, such as the AN/APN-22 and AN/APN-117, utilize the Radar Test Set AN/APM-66. This test set also provides a means of calibrating, checking the operation, and facilitating the maintenance of both sets. A unit of this test set (Delay Line MX-1381/APM-66) provides a "GO-NO GO" test for line maintenance of either altimeter. The electronic control amplifiers and the transmitter-receiver units must be calibrated on the test bench as a matched set for proper operation in the aircraft.

RADIO RANGES AND RELATED FACILITIES

A radio range is a CW station, whose radiation produces directional courses or "tracks." These courses remain stationary with respect to the surface of the earth, and serve to guide aircraft over long distances.

OMNIDIRECTIONAL RANGE

As the name VOR (VHF, omnidirectional range) implies, the omnidirectional or all-directional range station provides the pilot with courses from any point in its service area. It produces an unlimited number of radials, any one of which is a radio path connected to the station. The radials should be considered as lines which originate at the station and radiate outward like the spokes of a wheel. Operation is in the VHF portion of the radio spectrum with the result that interference from atmospheric and precipitation static is negligible. The navigational information is presented in a visual form, is constantly available, and is provided regardless of the position of the aircraft in the service area.

The basic provision of the VOR facility is a means of determining the angular position, or azimuth, of an aircraft with respect to the station. This measurement is made in the airborne receiver which determines the phase difference of two 30 hertz tones derived from two signals radiated from the range station transmitting antenna array. One signal, called the reference phase, is broadcast in a nondirectional radiation pattern. At all points on a circle having the station as its center, corresponding parts of this 30 hertz modulation occur at exactly the same time. Since the phase of this signal is independent of azimuth, it is used as a reference for comparison with another 30 hertz variation derived from a signal called the variable phase.

13672

197

13672

The variable phase signal is radiated in a figure-of-eight pattern which revolves about the transmitting antenna in a way somewhat similar to a rotating searchlight beam. The pattern consists of a positive and a negative lobe which turn together at 1,800 rpm (30 rps). As a result of the rotation of the pattern, the signal induced in the receiver is amplitude modulated with 30 hertz variations. The receiver develops this tone and compares it with the reference signal. The amount of phase difference between the two depends on the location of the aircraft with respect to the station. A phase measuring circuit in the receiver enables the pilot to determine the magnetic bearing, and also to select and fly a range course to the station on any desired bearing.

As shown in figure 17-4, the VOR transmitter is modulated both by a 9.96 kHz subcarrier and by an additional component either of voice or the station identification code characters. The subcarrier is frequency modulated at 30 Hz and is generated by a notched tone wheel rotating in a magnetic field. The purpose of the subcarrier is to provide a means for separating the 30 hertz tone of the reference phase from the variable tone of the same frequency.

The modulated output of the transmitter is applied both to a modulation eliminator and to the center loop antenna of a five-element array. There it is radiated to form the reference phase signal. The modulation eliminator is a clipper which removes the amplitude modulation from the carrier. The unmodulated output is fed to a

Figure 17-4.–Omnirange system fundamentals.

13673

capacity goniometer which serves as a mechanical sideband generator. The goniometer is a motor-driven, double capacitor in which one set of stator plates is displaced 90° from the other set. The rotor plates to which the RF signal is applied are driven at 1,800 rpm (30 rps).

Two outputs are derived, one from each set of stator plates. These two signals contain modulation components (30 Hz) which differ in phase by 90° because of the capacitor plate relationship. One output is fed to one pair of diagonally opposite loop antennas, and the other is fed to the remaining pair of loops in the square array. Each pair of corner antennas produces a figure-of-eight radiation pattern. These two patterns are displaced from each other by 90° both in space and in time phase. The resultant pattern is the sum of the two crossed figure-of-eight patterns and consists of the rotating field described above.

Figure 17-4 shows in simplified form the essential elements of the receiver which enable the pilot to select and fly a range course to the omnidirectional station. In the VOR transmitting system, the reference and the variable signals are in phase along the 0° radial (bearing due north of the station). The phase difference between the signals changes proportionately with the change in bearing to the station. The airborne receiver measures the magnetic bearing of the range station by the following general method:

1. The reference and variable signals are received and separated.

2. The two signals are then applied to a phase bridge containing a zero-center meter (the vertical pointer instrument used with the ILS localizer beam).

3. The reference signal is applied through a phase shifter, or course selector, equipped with a dial calibrated in degrees from 0 to 360.

4. The reference signal is shifted (in phase) by adjustment of the calibrated course selector until the phase bridge is brought to a zero indication. The amount of phase shift required to zero the bridge is proportional to the magnetic bearing of the range station.

To fly a given course to the station, the pilot sets the phase shifter until the calibrated dial reads the desired course. With this setting the reference signal is phased so that a balanced condition of the course indicator needle is shown as long as the aircraft is on the selected radial. To follow the radial to the station (usually described as "flying inbound"), the pilot flies so as to keep the vertical needle of the course indicator in the center position. The terms RADIAL and COURSE do not always mean the same thing. To fly INBOUND on the 045° radial, the pilot must fly a course of 225°. To fly INBOUND on a course of 130°, the pilot must use the 310° radial.

As indicated in figure 17-4, the receiver is an ordinary superheterodyne through the second detector. Following the second detector, filter circuits separate the 9,960 hertz subcarrier and the variable phase 30 hertz signals. The FM subcarrier is then applied to an FM detector which recovers the 30 hertz reference voltage. After passing through the phase shifter (course selector), the reference voltage is combined with the variable signal in the phase meter circuit.

The phase meter is a bridge which is balanced (indicated by a center position of the course indicator) when the two 30 hertz variations applied to it differ in phase by 90°. With this relation, the vector sum of the voltages in the upper half of the circuit is equal to the vector sum of those in the lower half. The two sums are converted into d.c. by rectifiers and applied to the zero-center instrument with opposite polarity.

The phase shifter contains two transformer windings mounted at right angles, and these two are fed with two components of the reference signal. A third winding rotates inside the other two coils, and a voltage is induced in it with a phase angle which depends on the rotor position with respect to the two primaries. The rotor coil is attached to a counter type dial which is calibrated in degrees to indicate the magnetic bearing to the omnirange station. A manually adjustable set knob is used to position the rotor for the desired magnetic course.

The vertical pointer of the course indicator remains in the center as long as the aircraft is on the selected course line, whether inbound or outbound. (This results from the fact that there are two positions of the phase shifter which will balance the bridge circuit.) Since the course line consists of two radials which are reciprocals of each other, an indicator is needed so that the pilot will know which radial (that is, which side of the station) he is on. The TO-FROM indicator tells the pilot whether the selected course line,

13674

once he is on it, will take him to the station or from the station.

For example, suppose the aircraft is on the 90° radial. To fly to the station, the pilot takes a heading of 270° and dials 270° on the course selector. The TO-FROM indicator reads TO while the aircraft is approaching the station from the east. After passing over the station, continuing westbound, the TO-FROM indicator reads FROM.

INSTRUMENT LANDING SYSTEM

The instrument landing system, (ILS), one of the facilities of the federal airways, operates in the VHF portion of the spectrum. The entire system consists of a runway localizer, a glidepath signal, and marker beacons for position location.

The localizer equipment produces a radio course alined with the center of an airport runway. The on-course signal results from equal reception of two signals-one containing 90 hertz modulation, and the other containing 150 hertz modulation. On one side of the runway centerline, the radio receiver develops an output in which the 150 hertz tone predominates. This area is called the blue sector. On the other side of the centerline, the 90 hertz output is greater. This area is called the yellow sector.

AT.308

Figure 17-5.–Tone localizer pattern and instrument indications.

In the aircraft receiver, the output circuit contains a balanced rectifier connected to a zero-center microammeter which remains centered as long as equal amounts of the two tones are present. Deviation of the aircraft to either side of the final approach course results in deviation of the indicator as shown in figure 17-5.

The localizer transmitter operates at about 110 MHz. The transmissions are made from an antenna array containing eight loops situated about 1,500 feet from the end of the runway. Three kinds of transmissions are made. Six of the loops radiate sideband energy only. Sidebands containing 90 hertz modulation and those bands containing 150 hertz modulation are separated by a sharp null directed along the centerline of the runway. Two of the loops radiate the carrier wave containing equal amounts of 90 hertz and 150 hertz tones, and this signal is sent along the null separating the sectors. Signals are received in any location; but as indicated in the figure, only along the runway centerline are the 90 hertz and 150 hertz tones received in exactly equal amounts.

The glidepath is a radio beam which gives vertical guidance to the pilot, assisting him in making the correct angle of descent to the runway. Glidepath signals are radiated from two antennas which are driven by a crystal-controlled transmitter operating at about 330 MHz. The power output is about 25 watts.

One antenna radiates a beam which is very broad in the vertical plane. This beam contains signals modulated by a 90 hertz tone. The other antenna emits signals modulated at 150 hertz in many lobes which are very narrow in the vertical plane. The undesired lobes are too high (fig. 17-6) to be encountered in a normal approach. The glidepath is an area of intersection between the broad 90 hertz lobe and the lowest of the 150 hertz lobes. In this area, which is a conical beam, the receiver develops equal amounts of 90 hertz and 150 hertz signals in the output. The beam is inclined about 2.5° with the horizontal.

The glidepath receiver is a crystal-controlled superheterodyne which is powered entirely from a 28-volt, d-c source and requires no high voltage power. The receiver audio output containing the 90 hertz and 150 hertz tones

13675

ASSIGNMENT:

You will have issued to you an old, dull ruling pen and an 8" x 11" buff drawing paper. Draw a $\frac{1}{2}$-inch border all around the paper and proceed to draw a single set of lines as shown in half the drawing below. When this is completed, clean the pen and sharpen it on the oil stone. Turn the buff paper around and draw the other set of lines. If your pen has been sharpened properly, you will notice a vast improvement.

1865 1364

is filtered, and the two signals are rectified separately. The resulting direct current is applied to a zero-center microammeter which indicates by means of a horizontal pointer. (The localizer and glidepath indicators are actually mounted on the same instrument. However, in many military installations the glidepath equipment is not employed.) The pilot flies the glidepath by keeping the horizontal pointer in the center of the dial.

Figure 17-6 shows how the glidepath would appear. The cross section is shown from the runway to a distance of 10 miles. At that range the glidepath appears to be 920 feet thick (vertically) and 4,600 feet wide. By keeping both pointers centered, the pilot may fly to the runway without seeing the ground. However, once over the runway, the pilot must be able to see the runway in order to land.

Marker beacons and compass locators are used in connection with the instrument landing system. The markers are signals which indicate the position of the aircraft along the approach to the runway. Two markers are used in each installation. The location of each is identified both by tone modulation and by a signal lamp. The outer marker is located about 4.5 miles from the end of the runway. The signal is modulated by a 400 hertz tone and is keyed in long dashes (two dashes per second). The inner marker, located at a distance of 3,500 feet, is modulated at 1300 hertz (a higher pitched tone) and is keyed with alternate dots and dashes.

Compass locators are low-power nondirectional beacons which provide signals for automatic direction-finding equipment. They operate between 200 kHz and 400 kHz and are located near the marker beacon transmitters. The locator near the outer marker is coded with the first two letters of the localizer transmitter identification letters, and the locator near the inner marker employs the last two letters of the call signal.

DISTANCE MEASURING EQUIPMENT

Eventually, each omnirange station will be equipped with distance measuring equipment (DME). By means of this facility, the pilot is provided with constant visual indication of his distance from the range station; and the combined VOR and DME data include all the information required for point-to-point navigation. These data consist of exact knowledge of the

AT.309

Figure 17-6.–Cross section of ILS course.

13676

distance of the aircraft from one or more range stations together with the direction of each.

The operation of DME units is similar to that of IFF. The airborne unit, called the interrogator, transmits a train of short pulses which are received by the ground unit, called a transponder. After reception of the challenging pulses, the ground station uses suitable circuits to shape them into trigger impulses which modulate a pulse transmitter to send a reply to the aircraft. Upon reception of the signal by the interrogator, the elapsed time between the challenge and the reply is measured. This interval is a measure of the distance separating the aircraft and the transponder station.

The challenge sent by the aircraft consists of spaced pulses in the 960-990 MHz band. The ground station equipment is set to accept only those signals which have the correct spacing and which are on the correct frequency. The frequency and the pulse spacing characteristics define a challenge channel. The reply consists of a train of RF pulses in the 1185-1215 MHz band. The combination of the challenge and reply channels is called an operating channel.

Up to 50 aircraft can use the same ground station to obtain DME information without interference.

A typical airborne unit, shown in block diagram form in figure 17-7, consists essentially of timing circuits, search and tracking circuits, and the indicator meter.

The timing circuits measure the time interval between the transmission of a challenging pulse from the transmitter and the reception of the corresponding reply pulses. As in radar operation, this time value is a measure of the distance separating the aircraft and the station.

The search circuits operate by causing the equipment to seek out a reply after each challenge. Briefly, the search function is as follows: The receiver is triggered on by gating circuits and operates for a very brief period of time after each challenge. The gate pulse which activates the receiver is separated from the

AT.310

Figure 17-7.–Block diagram of a typical DME system.

13677

challenge by an interval of time delay, T. Interval T is made to vary between 0 and 1,200 microseconds, corresponding to a range of distances from 0 to approximately 112 miles. The receiver goes into operation after each challenge, but is delayed by a different interval of time after each emitted signal. The receiver can accept beacon replies only when the delay time, T, is equal to the time required for a challenge signal to reach the station and the reply to return. When the time delay is such that the station reply is received, the search circuits are disconnected and the tracking operation begins. During tracking, the receiver holds the signal which it has found. When this occurs, the distance of the station is indicated on the dial of the indicator. This is accomplished by measuring the delay time, T. The value of T is controlled by a voltage to which it is directly proportional. When the search circuits have discovered a reply, the control voltage is applied to the voltmeter which is calibrated in miles.

The tracking circuits of the equipment adjust the time of operation of the receiver so that the receiver station reply is accepted even though the distance between the aircraft and the ground station is constantly changing. In tracking operation, the receiver is controlled by the action of two gating impulses–the wide gate (20 microseconds) and the narrow gate (10 microseconds). A signal received in the wide gate increases the delay time, and one received during the narrow gate decreases it. Thus the two control gates effectively bracket the reply signal and keep the receiver operating at the time when the reply pulses arrive. As a result, the distance meter continually indicates the number of miles between the aircraft and the station.

The automatic search circuits can be started again when the pilot wishes to track on another station. If the new station is more distant than the first, a release switch is pressed which causes the delay to increase. The search circuits then begin operating to seek out the delay time corresponding to the station. If the alternative beacon is nearer than the first, a zero switch is pressed which causes the delay time to start again from zero before resuming search operation.

A pilot lamp, found in some installations near the DME meter, indicates the presence or absence of a signal, and is illuminated if no signals are present. The station transmissions are gap-coded; that is, the replies are arranged so that intervening spaces form the Morse code letters assigned to identify the station. When the signals are being received, the pilot lamp flashes on and off, giving the station code identifier. When the aircraft is at a distance beyond the operating range of the station, the light burns continuously to warn the pilot that the meter reading is no longer the true distance but is the distance at which the signal was last received.

TACAN SYSTEM

TACAN, standing for TACtical Air Navigation, is an air navigational system operating at UHF frequencies to provide aircraft with continuous accurate range and bearing information. The system consists of an airborne UHF transmitter-receiver (AN/ARN-21) and a surface station (AN/URN-3). Bearing information is accurate to within 0.25°. The maximum slant range is 195 nautical miles with an error of less than 1,000 yards. The error at close range is less than 200 yards. The system has 126 two-way operating channels in the range of 962 to 1213 MHz. Each channel uses two separate frequencies spaced 63 MHz apart. Adjacent channels are separated by 1 MHz. Each of the 126 channels is capable of providing full service without interference to over 100 aircraft. The method used by the system to transmit bearing information is similar to that of the VOR, and the range information is similar to that of the DME. A simplified block diagram of a complete system is shown in figure 17-8.

Both the AN/ARN-21 and the AN/URN-3 contain a receiver and a pulsed transmitter. The surface station continually transmits signals consisting of randomly spaced pulse pairs, pulse-pair distance replies, and evenly spaced and coded groups of paired pulses. Due to the antenna configuration and rotation, all of these signals arriving at a given location are amplitude modulated at both 15 and 135 Hz. The surface station transmits approximately 3,600 pulse pairs per second. The main azimuth reference burst is transmitted each time the antenna passes a given azimuth (usually magnetic east) and consist of 12 pulse pairs with 30 microseconds between pairs. The antenna rotates at 15 rps (12 x 15 equals 180 pulse pairs per sec-

13678

AT.311

Figure 17-8.–Simplified block diagram of the TACAN system.

13679

ond). The auxiliary reference bursts are transmitted eight times during one revolution of the antenna and consist of 6 pulse pairs with 24 microseconds between pairs (8 x 15 x 6 equals 720 pulse pairs per second). This gives a total of 900 pulse pairs per second used for azimuth reference signals. The remaining 2,700 pulse pairs per second are transmitted at random. Some of these random pulse pairs are controlled by distance interrogation signals from aircraft to give distance replies. Also, at intervals (usually every 37.5 seconds), the random pulse pairs are replaced by pulse pairs with fixed spacing arranged to form Morse code.

Whenever the surface station receives a distance interrogation pulse-pair from any aircraft, it transmits a pulse-pair reply (using one of the 2,700 random pulse pairs) exactly 50 microseconds after receiving the interrogating pulse pair.

TACAN ANTENNA

The AN/URN-3 antenna consists of a central stationary driven element with a rotating array of one main parasitic reflector element and nine auxiliary parasitic reflector elements to give an antenna pattern that is a combination of a cardioid with nine lobes superimposed on it. (See fig. 17-9.) Every time the main lobe of the antenna passes magnetic east, the AN/URN-3 transmits the main reference burst of 12 pulse pairs (30 microseconds between pairs). Every time one of the other eight auxiliary lobes passes magnetic east, the AN/URN-3 transmits an auxiliary azimuth reference burst of 6 pulse pairs (24 microseconds between pairs). Since the pattern is rotating at 15 rps, an aircraft in the position shown would receive a signal containing pulse pairs amplitude modulated at both 15 Hz and 135 Hz. (See fig. 17-10.) One is called the 15 Hz variable bearing signal, and the other is called the 135 Hz variable bearing signal.

AT.312

Figure 17-9.–Rotating antenna pattern of AN/URN-3.

AIR-TO-AIR-TACAN

The original TACAN system was limited to an air-surface application–no provisions were made for air-to-air ranging. However, the newer concept of TACAN includes this feature and uses the AN/ARN-21D or the AN/ARN-52(V) equipment.

In the AN/ARN-21D, the air-to-air link functions primarily because of a modification permitting "image frequency" reception. Ranging is made possible by adding a transponding function to the airborne equipment. Both ends of the link display distance information simultaneously; therefore, the technique is called "bilateral ranging." The TACAN ground station is not involved in the air-to-air link.

The airborne sets receive on frequencies displaced 63 MHz from their transmitting frequencies. Considering the ground station system as normal TACAN, the air-to-air system uses the "image" frequency. This idea is illustrated in figure 17-11.

In both systems, the transmit and receive frequencies are separated by 63 MHz. However, in the normal system, reception is below transmit frequency for channels 1-63 and above for channels 64-126. For the air-to-air (A/A) system, these situations are reversed. Thus, any AN/ARN-21D set for normal operation will not respond to A/A transmissions, regardless of the channel selected. (See fig. 17-12.)

Careful study of figure 17-12 (A) illustrates the following details of TACAN operation:

1. Aircraft A and the ground station set to the same channel, aircraft set on normal mode, operation is normal. Aircraft B and C are not involved.

2. Aircraft B and C are set to channels separated by 63 MHz both aircraft on air-to-air mode, bilateral ranging is performed. Aircraft A and the ground station are not involved.

3. Aircraft A and C are set to the same channel, but on different modes. They do not respond to interrogations by the other aircraft.

AT.313

Figure 17-10.–Signal received by an aircraft at 150°.

Figure 17-12 (B) illustrates the simultaneous ranging of aircraft A and C on aircraft B, but not on each other. Aircraft B will indicate the range to one of the aircraft (which one is mere chance).

In order to prevent aircraft from replying to replies, the interrogation consists of pulse pairs, while replies consist of single pulses. Replies are made only to pulse pairs.

AN/ARN-21 (Series) TACAN Receivers

Radio Set AN/ARN-21B is the general airborne TACAN unit used for air-to-surface operation as described previously. When modified to incorporate the air-to-air capability, the equipment is designated AN/ARN-21D and functions in either mode as selected from the control unit. In principle, operation is similar

AT.314

Figure 17-11.–TACAN frequency spectrum.

13681

to the AN/ARN-52(V) discussed in the following section. The AN/ARN-52(V) is a newer and somewhat improved airborne TACAN unit.

The AN/ARN-21 (Series) uses a 42 MHz oscillator and 42 crystals to produce the frequencies needed for the 126 channels.

The AN/ARN-52(V)

The AN/ARN-52(V) contains additional features and improvements, even though it is slightly smaller and approximately 20 pounds lighter than the AN/ARN-21. In addition to the air-to-surface and air-to-air features, the AN/ARN-52(V) contains built-in range and bearing mechanical modules. Minimum power output has been increased to 1.5 kw, and the range readout has been increased to 300 miles. It also uses 126 crystals—one for each channel, instead of the 42 MHz oscillator and 42 crystals used in the AN/ARN-21B. In air-to-air mode, it responds to a maximum of five interrogating aircraft.

The AN/ARN-52(V) can be adapted to supply and process distance and bearing information for use in various indicators, automatic pilots, and computers. The indicators used in conjunction with this equipment include a bearing-distance-heading indicator (BDHI) such as the ID-663/ARN, a course indicator such as the ID-387, a radio bearing indicator such as the ID

AT.315

Figure 17-12.–TACAN system operation.

250, and/or a distance indicator such as the ID-388.

The AN/ARN-52(V) operates in any of three modes. It can receive bearing and station identity information; receive range, bearing, and station identity information, or receive and transmit bilateral air-to-air ranging information.

As installed in an aircraft, the AN/ARN-52(V) uses two antennas mounted in such a manner that any "blind" spot of one antenna is covered by the other. An automatic antenna selector circuit connects the RF circuits to that antenna which provides a usable TACAN signal. In the absence of a usable signal, this circuit switches the equipment back and forth between the two antennas. When a suitable signal is received at one antenna, the equipment is locked to that antenna. Loss of a usable signal initiates a memory period to prevent loss of lock resulting from short-duration transient conditions.

The basic frequency of the selected crystal (42.7 to 47.9 MHz) goes through several stages of multiplication and amplification to produce two outputs at the transmission frequency. One signal is amplified, pulse modulated, and radiated from the antenna. The other signal is used in the crystal mixer as a local oscillator signal to produce the 63 MHz IF signal.

For further details concerning TACAN equipments, refer to the applicable technical manuals.

BENCH TEST AND ALINEMENT

The majority of aircraft TACAN equipment is tested and alined with the use of Radio Test Set AN/ARM-22A. This test set provides air-to-air (A/A) testing capabilities and simulates navigational signals that are normally provided by the Radio Set AN/URN-3 (or other TACAN station radio transmitter), a part of the TACAN system.

The AN/ARM-22A can simulate fixed or variable ranges from 0 to 198 miles, all bearings from 0° to 360°, and tone for operation of the identity circuits of the aircraft TACAN equipment. In addition, the test set can transmit these simulated signals to equipment being tested on any one of 126 preselected channels.

The radio test set may be mounted on a mobile dolly to facilitate flight line testing of airborne components.

When the radio test set is used in conjunction with Test Set Indicator AN/ARM-31, the capabilities of the equipment are increased. The simulated information sent to and then processed by the equipment being tested is displayed on the test set indicator in the AN/ARM-31. This enables the operator to test individual components of the aircraft equipment.

LORAN

The word LORAN is formed from the words LOng RAnge Navigation. It is a navigational system developed primarily to provide a means for making geographical fixes by the use of long range radio signals. The system is a valuable aid to navigation, since loran fixes can be made quickly and accurately both by night and day. It is reliable for both air and surface navigation under most weather conditions. Loran signals can often be received even during storms, except those involving severe electrical disturbances. The principal value of loran lies in its capability of continued operation during conditions which make celestial navigation difficult or impossible. Such conditions include any situation in which the stars are not visible.

PRINCIPLES OF LORAN

In principle, loran differs from radar in that the airborne unit simply receives radio pulses broadcast from ground stations, and no reception of echo signals is involved. The basic loran measurement is that of time difference of arriving signals with no regard to the direction from which they arrive; hence, the complicated directional antennas used in radar equipment are not necessary. Despite these differences, however, loran is closely related to radar since it uses pulse type equipment, and it employs radar techniques of time measurement. Also, visual displays of the signals received are made on cathode-ray tubes used as indicators.

The basic principle of the system is illustrated in figure 17-13. Two stations are necessary to establish a loran line of position. The master station (A) emits a continuous series of uniformly spaced pulses at a stable pulse recurrence rate. The slave station (B) sends out a similar series of pulses which are

13683

synchronized with the master pulses. The master and slave stations are usually 200 to 400 miles apart. The line joining the two stations is called the baseline, and the perpendicular at its center is called the centerline. The baseline extension is a straight line drawn beyond either station as a continuation of the baseline.

Assume that the two stations are sending out pulses simultaneously; then at any point along the centerline, the two signals arrive at the

AT.316

Figure 17-13.–The principle of loran.

13684

same instant (since all points of the line are equidistant from the two transmitters). If an observer is located nearer station A than station B, the A pulse arrives at his position first, followed (after a measurable time interval) by the corresponding B pulse. By moving to different positions located in the same vicinity, the observer could record the time interval (difference in arrival time of the A and B pulses) corresponding to each position. If several positions having the same time interval were joined by a smooth curve, the curve thus traced would be a line of position for station pair A and B.

The difference in the time of arrival of the pulses corresponds to the difference in distance from the stations, and can be accurately calculated and plotted on a chart. Selected line of position curves may be drawn by connecting points of equal computed time or distance values. Each curve so constructed has the shape of a hyperbola, which is the mathematical name for a curve consisting of points whose difference in distance from two fixed points (in this case, A and B) remains constant. Thus, loran is called a hyperbolic system of navigation.

A large number of lines of position are drawn for each pair of transmitters as shown in figure 17-14. Each line is labeled with a number indicating the time interval in microseconds between the arrival of the corresponding loran pulses.

In (A) of figure 17-14, zero time difference exists along the centerline, while maximum time difference exists along the baseline extensions. Lines with equal time difference may be noted on each side of the centerline, since there is no way to determine which pulse is received from which station. In actual practice, however, the signals are not emitted simultaneously. The slave station pulse is delayed so that, at any point, the master station pulse is received before the corresponding slave pulse. As a result, each curve of the family has a discrete time interval value as indicated in (B).

The delay of the slave pulse includes several increments. The master station transmits a pulse to initiate the sequence of events. An interval of time elapses during which the signal reaches the slave station. The slave station receives the impulses and waits an initial period of time (equal to one-half the pulse recurrence interval) plus an additional period of time (called the coding delay). It then emits a pulse. The sum of the travel time, half the recurrence interval, and the coding delay is called the absolute delay. As a result of the delay, the master pulse always precedes the slave signal at any point of reception. The difference in arrival time is maximum along the baseline

AT.317

13685

Order of Inking Lesson 3

OBJECTIVE: To learn the proper procedure when inking.

RELATED INFORMATION:

When inking, for best results always use black drawing ink (for this prints best) and be sure your pens are sharp and in good condition. In the event that an ink line may have to be removed, use a hard ink eraser, being careful not to go through the paper or cloth. Some draftsmen prefer to use a sharp knife or razor when erasing, but in either case, after the erasure is made, rub some pounce into the erased area. This will help prevent the ink from running when redrawing over the area. When inking, attempt to use the following order:

1. Ink in all full-line circles, beginning with the smallest.
2. Ink dotted circles and arcs.
3. Ink any irregular curved line.
4. Ink straight full lines in this order - horizontal, vertical, and inclined.
5. Ink straight dotted lines in the same order.
6. Ink center lines.
7. Ink extension and dimension lines.
8. Ink arrowheads.
9. Ink section lines representing cut surfaces.
10. Ink in the dimensions.
11. Ink the border.
12. Check the inked drawing.

extension beyond the master station and minimum on the baseline extension beyond the slave station.

LORAN NAVIGATION

The loran navigation network is designed to cover a vast ocean area. This fact, coupled with the long distance usage, requires a fairly large number of stations. However, loran stations operate in a crowded portion of the radio spectrum; therefore, only a few specific frequencies are available. At the present time, only 3 channels are used, but as many as 24 station pairs may be operated on each. This is made possible by using a different pulse recurrence rate for each station pair on any channel. The equipment can thus distinguish between various pulse pairs and measure the time interval for any selected pair—Other pulse pairs are not synchronized with the CRT sweep, and therefore drift across the screen.

In order to determine a position by loran, it is necessary to obtain intersecting lines of position from two or more station pairs, then refer to a special loran chart to locate the position of that intersection.

The U.S. Navy Hydrographic Office publishes loran charts (which are standard Mercator charts with loran lines of position superimposed). The use of the chart in obtaining a "fix" is illustrated in figure 17-15.

A loran chart shows the lines of position of one station pair crossing those of another. In many installations, the two pairs consist of a single master station operating in conjunction with two slave stations. This is called double-pulsed transmission and is the type represented in figure 17-15. The common master station emits two sets of pulses. Each set is synchro-

AT.318

Figure 17-15.–Obtaining a loran fix.

13686

The two readings given by the revolution counters are plotted on loran charts and enable the operator to determine his location.

The electron beam in the indicator tube traces two time baselines, one above the other, as indicated in figure 17-16. Moving from left to right, the beam slowly traces the upper line in a period of time equal to one-half the pulse recurrence interval. It quickly retraces, jumping to the left and below. It then traces the lower baseline in one-half the recurrence interval before rapidly returning to the start of another top line.

The master station pulse is superimposed on the upper baseline, and the slave pulse appears on the lower. When the receiver is correctly adjusted, the station pulses are displayed above pedestals (rectangular deflections) in the time baselines. The pedestals indicate portions of the display which can be expanded and examined in greater detail for accurate measurement. The time difference to be measured is represented by the horizontal distance between the master pulse on the left and the slave pulse below it to the right. This method of measuring the time difference automatically cancels the fixed delay of one-half the recurrence rate by which the slave pulse was retarded during transmission.

AT.319

Figure 17-16.–Time difference measured on a a loran indicator.

Theory of Operation

The APN-70 receiver assembly is composed of three major units: the RF receiver, the timer, and the deflection units. These sections are shown in block diagram form in figure 17-17,

AT.320

Figure 17-17.–Receiver, AN/APN-70, block diagram.

13688

which also includes the components of the loran indicator.

RF RECEIVER UNIT.–This portion of the loran receiver is a superheterodyne system, which contains an RF amplifier, a converter, two IF amplifiers, a detector, and a video amplifier. Loran signals are received from the antenna coupler by the RF amplifier, a tuned-grid, tuned-plate circuit. The output of the amplifier is applied to the converter stage.

One section of the converter stage is used as a crystal oscillator circuit that produces mixing voltages. The IF output of the converter, is amplified in the two IF amplifiers and fed to the detector. The resulting video pulses pass through one stage of amplification and are coupled through a cathode follower and the video section of the indicator to the vertical deflection system of the cathode-ray tube.

TIMER UNIT.–This unit generates a series of pulses serving as the time base of the equipment and produces the variable-delay intervals used to measure the time differences of the loran pulses. Also, to insure that the receiving set and the transmitter system are operating at the same recurrence rate, the timer contains circuits for synchronizing the two.

The timing standard in the receiver is an 80 kHz crystal oscillator from which is derived (either directly or indirectly) the time bases for the timer, delay, and deflection circuits. The oscillator is synchronized with the time base of the loran transmitter by the action of the automatic drift control circuits. The oscillator can be changed in frequency over a narrow range by a reactance tube whose d-c input grid voltage assumes a value corresponding to the degree of synchronism of the receiver circuits with the incoming loran pulses. The grid voltage of the reactance tube is produced by a discriminator tube which compares the repetition rate of the incoming master and slave pulses with the master and delay pulse pedestals from the receiver-indicator. (The master and delay pulses have a pulse rate set by the timer.) Any variation in the two rates produces a d-c bias on the control grid of the reactance tube which, in turn, corrects the oscillator frequency and the resulting pulse rate derived from it. Thus, automatic drift control is established.

The sine-wave output of the crystal oscillator is shaped to produce a sharp negative driving pulse which is applied to the counter circuits. The electronic counter contains 12 identical multivibrators and 10 identical interstage amplifiers. Each counter stage is a binary counter (divides the input pulse rate by 2). The first 11 of these stages, together with 10 interstage amplifiers, are used to obtain the repetition rate. The 12th stage is driven by the output of the repetition rate circuits to obtain a square wave which is equal to the recurrence rate of the loran transmitting stations selected.

The first multivibrator of the counting series is triggered by 80 kHz pulses derived from the pulse forming circuits. The output of the first stage is fed to the grid of the first interstage amplifier tube which drives the second multivibrator. This sequence is repeated throughout the first 11 stages so that the overall division ratio is 2,048 to 1; hence, the counter chain gives one output pulse for every 2,048 pulses fed into it when all 11 counters are used.

The repetition rate circuits accept the output of the counter section and produce the reset pulses which determine the time at which the counter stages reach the count selected by the position of the recurrence rate switch. At that time a pulse is generated to reset the counter chain for the next cycle and to drive the 12th stage. The position of the recurrence rate switch may be set for any one of the 24 loran repetition rates. In addition, the repetition rate circuits supply trigger pulses to the fixed-delay circuits, the time-sharing gain circuits, and to the sweep circuits in the indicator unit on position 1 of the function switch.

The W- and Y-delay indicating systems consist of dials, switches, gear trains, gating tubes, wave shapers, goniometers, pulse formers, and thyratrons. These systems are connected to stages 3 through 11 of the binary counter chain and to the 12th stage. Each delay system produces one output pulse during each L period. The occurence of this output can be varied uniformly and continuously (after the second reset) to start the succeeding loran cycle by means of a handcrank. Two dials indicate the microseconds of delay produced at the thyratron of each system. The W and Y systems are identical in construction and operation except that their outputs appear in successive L/2 periods for operation with low frequency loran signals (dual presentation). With high frequency

13688 13689

(single presentation) loran reception, only one delay system operates, as determined by the setting of the W-Y switch.

DEFLECTION UNIT.–In addition to the low voltage power supply, the deflection chassis contains circuits that receive signals from the timer unit. These signals are used to synchronize and trigger waveforms that perform the following functions:

1. Generate three independent bias voltages for the three time-sharing gain circuits.
2. Generate waveforms to drive the sweep generator in positions 2, 3, 4, and 5 of the function switch.
3. Generate trace-separation waveforms when required by the function selected at the control panel.

In single presentation, the time-sharing gain controls enable the operator to adjust the receiver gain to an independent level on each trace appearing on the indicator screen. Either the W- or the Y-delay system may be independently selected by a control switch. In dual presentation, the delay reading and the gain setting of one pair of loran stations may remain on one counter dial and gain control knob while the operator is matching a second pair of loran pulses using the second delay system. The output of the time-sharing gain circuits supplies bias to the RF and IF stages of the RF receiver unit.

The trace-separation circuits are connected to the lower vertical deflection plate of the cathode-ray tube. The fixed-delay circuits provide a 1,625-microsecond delay for the trigger governing the appearance of the master pedestal. For dual presentation, one trigger signal for every L/2 interval is provided; in single presentation, only one trigger signal for every alternate L/2 is required.

The pedestal circuits receive pulses from the fixed-delay and variable-delay circuits and generate waveforms to produce the master and slave pedestals. The output waveforms are supplied by a cathode-coupled, one-shot multivibrator which provides a pedestal of approximately 400 microseconds in positions 3 and 5 of the function switch in single and dual operation. The pedestal is 1,200 microseconds long in position 1, 2, and 4 of the function switch in single operation, or 1,750 microseconds long in dual operation. In position 1 of the function switch, the multivibrator generates the pedestals seen on the traces on the indicator tube. In other positions of the switch, the pedestals are used to generate the traces, and only the video signals present during the portion of the pedestal covered by the trace are shown on the indicator tube.

LORAN INDICATOR.–As shown in figure 17-17, the loran indicator contains the sweep circuits for developing the horizontal deflection voltages, the cathode-ray tube blanking circuits, the video circuits, and the cathode-ray tube. In addition, the assembly contains two high voltage rectifiers which supply d-c potentials for the CRT.

The sweep and blanking circuits are triggered by the reset pulses from the repetition rate circuits on function 1 and by the pedestal generator circuits on functions 2, 3, 4, and 5. A horizontal sweep generator supplies a sawtooth voltage waveform that is applied to the left horizontal deflection plate of the CRT. A portion of the output is also fed to a phase inverter stage to give an output wave 180° out of phase with the sweep generator output and which is applied to the right deflection plate thus providing a push-pull horizontal deflection.

The blanking circuit extinguishes the electron beam in the indicator tube during retrace intervals in which the grid in the indicator tube is driven highly negative with respect to the cathode. A d-c restorer diode clamps positive swings of the CRT grid to the voltage set by the brilliance control and establishes the level about which blanking takes place. An RC combination in the blanking circuit insures that the traces seen on the screen of the indicator tube are delayed until after the start of the sweep to remove irregularities in the initial parts of the sweep cycle.

Video signals derived from the RF receiver unit are amplified in the video circuits and are applied to the upper vertical deflection plate of the CRT.

The d-c voltages needed for operation of the CRT are supplied by low voltage regulator power supplies in the receiver unit and by the two high voltage rectifiers in the indicator assembly. One high voltage rectifier produces a d-c potential of 1,300 volts, positive with respect to ground, which is applied to the indicator tube through a cap connection. The other high voltage supply develops 1,300 volts, negative with respect to

13690

ground, and is applied to the cathode of the tube.

AUTOMATIC RADIO DIRECTION FINDER

Automatic direction finders are radio receivers equipped with directional antennas which are used to determine the direction from which signals are received. Most units of this class provide facilities for manual operation in addition to automatic direction finding (ADF). The automatic mode involves the use of motor-driven antennas which are positioned by means of closed-loop control circuits.

Before the development of radar and loran, radio direction finding was one of the principal means for determining the position of aircraft in bad weather. When an aircraft is within reception range of a radio station, the ADF equipment provides a means of fixing the position with fair accuracy. In addition to its usefulness as a navigational aid, the automatic direction finder is also employed as one of the basic devices of electronic countermeasure systems.

BASIC PRINCIPLES

When a conductor is cut by magnetic lines of force, or lines of flux, a voltage is induced in the conductor. In order to cut lines of flux, the conductor must be perpendicular or must have a component that is perpendicular to the lines of flux; and the relative motion between flux and conductor must have a component in a direction that is perpendicular to both the lines of flux and the conductor.

A vertically polarized wave has a vertical electric (E) field and a horizontal magnetic (H) field; therefore, the wave induces voltage in vertical conductors only. A vertical wire, or monopole, is the simplest type of antenna. When a vertically polarized radio wave induces voltage in a monopole, the induced voltage is in phase with the incident wave and is the same for all horizontal angles of incidence. (See fig. 17-18.) This similarity of response pattern, in all directions simultaneously, suggests the name omnidirectional (omni means "all") for this type of antenna.

AT.321

Figure 17-18.–Polar response of a monopole (sense) antenna.

Loop and Sense Antenna

The response of a loop antenna is different from that of a vertical monopole (called a sense antenna in this discussion). A rectangular single-turn loop with dimensions that are small compared to the wavelength of an incident radiation field is shown in figure 17-19. As the loop is rotated about the axis XX', the angle θ (between the plane of the loop and the direction of propagation of the wave) is changed.

If the loop is placed in a radiation field like the one shown in figure 17-19, the H vectors of the field cut the sides AB and CD at slightly different times because the wave travels at a finite speed. At any instant, therefore, the voltage induced in arm AB is slightly different from the voltage induced in arm CD. (The arms BC and AD are not affected by the H lines of a wave polarized at right angles to them, and do not contribute to the induced voltage in the loop because the horizontal members are parallel to the H lines.)

13691

AT.322

Figure 17-19.–Loop antenna in a radiation field.

If the loop is turned so that its face is perpendicular to the direction of arrival of the wave–that is, $\theta = 90°$, the sides AB and CD are cut by the H vector at the same instant. The voltages induced in arms AB and CD are then the same magnitude and phase and neutralize each other, so that no current flows in the antenna loop.

Since the magnetic field of the radio wave alternates at the frequency of the wave, the instantaneous flux density at any point along the path of arrival varies sinusoidally. Thus the voltage induced into arms AB and CD are sinusoidal voltages with a phase difference θ. The total loop voltage is the sinusoidal voltage which represents the integration of the sums of all the instantaneous voltages induced into the two arms. It may be shown mathematically that this resultant voltage is proportional to the cosine of θ.

The pattern of the response is similar to the figure 8. (See fig. 17-20.) It is by using the response as shown in this figure that all medium frequency direction-finding equipments obtain bearings.

The directional characteristic of the loop antenna is called a cosine, or figure-of-eight pattern. When the loop is oriented so that the received signal is a maximum, a small change in orientation produces a small change in signal. However, when the loop is at a null position, a small change in orientation of the loop produces a large change in output voltage. Furthermore, there is a reversal in phase of the signal as the loop passes through a null point. For these reasons, the null points rather than the maximum-response points are used in radio direction finding to obtain a line bearing or line of arrival of a radio wave.

As there are two null positions 180° apart, the loop can give a line of bearing (the actual bearing or its reciprocal) but cannot determine the absolute direction of the transmitter from the direction finder. The determination of absolute direction, or sense, is obtained by adding the output of a vertical sense antenna to that of the loop antenna. When the two antennas are properly connected, the combined response is not ambiguous.

Signal Comparison

The figure-of-eight pattern of a loop has two null positions for one incident radio wave (fig. 17-20). If the outputs of a loop and a sense antenna are combined in phase, the response of the two antennas is the algebraic sum of their individual diagrams. In order to produce a

AT.323

Figure 17-20.–Polar response of a loop antenna.

13692

given response, the magnitude of the individual signals must be considered. Refer to figure 17-21 for the following discussion.

This figure illustrates four possible responses caused by differences in the relative amplitudes of the sense and loop outputs. The desired response shown in (C) has one sharp null.

The output of the vertical sense antenna is independent of the horizontal direction of arrival of the wave, so it may be considered to have positive polarity. Because the phase of the loop voltage changes as the loop passes through a null, one-half of the figure-of-eight pattern may be said to have positive polarity and the other half to have negative polarity. The addition of the loop and sense curves gives the responses shown. The shape of the resultant curve is called a cardioid because of its similarity to a heart.

The output of the sense antenna is in phase with the radio wave. The output of the loop antenna, however, is 90° out of phase with the radio wave. This means that the loop output voltage is a maximum when the sense output is zero and vice versa. The cardioid pattern (which depends on the outputs being in phase) cannot be obtained unless the phase of either the loop or the sense antenna signal is changed by 90°.

The cardioid pattern produced by the combined loop and sense antenna can also be produced by the rhombic antenna. This type is used without a sense element.

DIRECTION FINDER SET AN/ARD-13

Direction Finder Set AN/ARD-13 is a low frequency radio navigation device that operates in the frequency range between 90 kHz to 1800 kHz. It is capable of receiving both AM and CW transmission within its operating range.

AT.324

Figure 17-21.–Response of the combined sense and loop antenna.

13693

The direction finder has three modes of operation which are selected remotely at the control unit. In the ANT mode, the RF input to the receiver is from the sense antenna; the direction finder operates as a nondirectional low frequency receiver. The RF input in the LOOP mode is from the loop antenna. The LOOP mode may be used for manual direction finding by rotating the loop for an audio output null or a tuning meter null. (A 180° ambiguity in direction is possible in the LOOP mode since the loop antenna pattern has two nulls 180° apart.) The direction from which signals are best received can be chosen manually from the control box by positioning the loop. In the ADF mode, the receiver combines signals from both the sense and loop antennas to determine whether the loop is pointed to the left or to the right of the signal source. The receiver commands clockwise rotation of the loop if the loop axis is pointed to the left of the signal source. Counterclockwise rotation is commanded if the loop axis is to the right of the signal source. Rotation ceases when the loop axis is pointed directly at the signal source.

The position of the loop is continuously transmitted to the bearing indicator. The bearing indicator reads the bearing to the station in the ADF mode, because the loop is kept pointed directly at the station. The bearing indicator combines the bearing information from the direction finder with navigation data received from other equipment. Audio signals in all three modes are supplied to the intercommunication system in the aircraft. The audio level to the ICS is varied manually from the control box. (See fig. 17-22.)

Theory of Operation

ANT (ANTENNA) MODE.–Radiofrequency signals from the sense antenna are coupled to the RF amplifier through the impedance-matching network in the sense antenna couplet. The only signal input to the RF amplifier in the ANT mode comes from the sense antenna; the loop amplifier and the balanced modulator are disabled. The oscillator and mixer convert the output of the RF amplifier to 455.7 Hz, the intermediate frequency of the receiver. The oscillator is tuned from the control box by the tuning servo. One of two mechanical filters passes the desired signal and attenuates the undesired signals. The broad filter provides selectivity of 3.1 kHz, and the sharp filter provides receiver selectivity of 1.5 kHz. The narrow band output of the mechanical filters is amplified by the IF amplifier and is applied to the detectors. The output of one detector is used as the automatic volume control (AVC) signal to limit the gain of the RF and IF amplifiers. The AVC signal is also applied to the tuning meter. The output of the other detector is applied to the audio amplifier. The audio gain control is bypassed in ANT mode and manual control of receiver gain is with the RF gain control. The audio amplifier increases the output of the detector to the level required by the ICS in the aircraft.

LOOP MODE.–Rotation of the loop antenna is controlled by the LOOP switch on the control box. The LOOP switch applies either of two phases of 400 Hz a.c. from the receiver to the loop rotating motor in the loop antenna. In practice, the operator uses the LOOP switch to drive the loop antenna to the position of minimum reception of the received signal. This position of minimum reception, which occurs when the loop antenna is pointed directly at the signal source, is called the null position. The angle of the transmitting station, with respect to aircraft heading, can then be read accurately on the bearing indicator. The RF output of the loop antenna is applied to the balanced modulator through the loop amplifier. The balanced modulator is unbalanced during loop operation and couples the output of the loop amplifier to the RF amplifier. Signals from the balanced modulator are the only input to the RF amplifier in the loop mode. The input to the RF amplifier is the same as in the antenna mode operation.

ADF MODE.–The RF output of the loop antenna has either of two phases relative to signals from the sense antenna. Phase A, as shown, occurs when the loop antenna is to the right of the null position. Phase B occurs when the loop is to the left of the null. The loop antenna has no output when in the null position. Either output phase of the loop antenna is modulated by a 47 Hz signal in the balanced modulator stage. The results of modulation for either phase input are shown.

The output of the balanced modulator is added to signals from the sense antenna by the RF amplifier. Note that there is a 180° difference in phase between the envelope of A, present

13694

when the loop antenna is to the right of the null, and envelope B, present when the loop antenna is to the left of the null. The output of the IF amplifier is amplified and detected, and is applied to the audio amplifier. The output of the audio amplifier is processed and applied to the 47 Hz amplifier.

The amplified 47 Hz component of the output of the audio amplifier is applied to the discriminator. The discriminator compares the phase of the 47 Hz signal from the 47-Hz amplifier with the reference phase from the 47 Hz oscillator. If the two are in phase, the discriminator applies a positive d-c level to the 400 Hz modulator. If the two are out of phase, the discriminator applies a negative d-c level to the 400 Hz modulator.

The 400 Hz modulator applies either phase A or phase B 400 Hz signal to the loop servo-amplifier, which is connected to one winding of the loop antenna drive motor; phase A if the d-c level from the discriminator is positive, and phase B if the input from the discriminator is negative. Phase A causes the loop antenna to rotate to the left, phase B to the right. Thus, the signal that drives the loop antenna motor

ASSIGNMENT:

Draw the object below on an 8" x 11" buff drawing paper in pencil. When completed, lay a sheet of tracing paper over the drawing and proceed to ink it, using the inking order described above.

1367

will always cause the loop antenna to rotate toward the null position.

The bearing indicator, electromechanically coupled to the loop antenna by synchros, reads the position of the loop and thus the direction to the signal source.

In the ADF mode, the RF gain control is inoperative. The audio gain control is used to vary the audio output level of the receiver.

ENVIRONMENTAL CONDITIONS

The environmental conditions under which an automatic direction finder must operate are important in determining the effectiveness of the equipment and the reliability of radio bearings. Satisfactory reception of radio signals depends on many factors. These factors may be broadly classified according to position, propagation characteristics, frequency characteristics, atmospheric conditions, and equipment capabilities.

Position

The farther a receiver is removed from the transmitter, the weaker the signal becomes. Pilots flying a radio beam sometimes use this gradual "fading" to determine the direction of the station. However, fading may result from many other causes, and is therefore frequently unreliable as an indication. In general, fading may result from the simultaneous reception of direct and reflected waves tending to cancel, thus decreasing signal strength.

Propagation Characteristics

A radiated electromagnetic wave tends to travel in a straight line, as discussed in chapter 5 of this manual. However, as discussed in chapter 9, there is a "bending" effect which occurs in radio wave travel. The actual amount of the bending depends on atmospheric density, temperature, and humidity. It is also affected by the electrical conductivity of the surface over which the wave travels.

In addition to the bending (refraction and diffraction), radio waves are also susceptible to reflection. Reflection may occur at the surface of the sea or land, from a mountainside, from ships, or from the ionosphere. It may have a relatively constant effect on the signal, or it may have a merely transient effect.

Some of the more important effects on radio wave propagation are the result of changes in the location and ionization of the ionospheric layer. This is discussed in basic form in Basic Electronics, NavPers 10087-B.

Night effect, occuring at both dusk and dawn, results from a shift in the ionospheric layer. At night, the height of the ionosphere is at a lower level with respect to the earth's surface than in the daytime. During the transitional intervals (dawn and dusk), the ionospheric layer bends as the height change progresses. This means that the radio waves strike the layer at a varying angle, and the reflection angle varies accordingly.

Shoreline effect results from variations of temperature and humidity and from differences in electrical conductivity between sea and land masses. The resultant changes in refraction affect the accuracy and reliability of radio bearings taken in this area.

Frequency Characteristics

As discussed in previous chapters of this course, the frequency of a radio wave affects its range, its propagation characteristics, and its susceptibility to interference. In general, range varies inversely with frequency–above some certain frequency limit, operational usage is limited to the line-of-sight range. Below that limit, the refraction index varies and the resultant maximum range is affected.

Atmospheric Conditions

In airborne applications, radio reception is affected by weather. In addition to the temperature, humidity, and density mentioned previously, reception is also affected by the electrical charge of the atmosphere. Lightning disrupts radiowave usage during the period of the flash for normal frequencies. Extremely high frequencies, however, may be usable in spite of lightning.

Two additional static disturbances are created as a result of the aircraft flying through the charged atmosphere. Precipitation static results when atmospheric particles strike the aircraft and create a static charge on the air-

13696

craft. Static discharge interference results when charges built up on the aircraft are discharged into the atmosphere. Normally, these conditions are relatively minor; but under certain atmospheric conditions, they may render the radio bearings unusable.

Equipment Capabilities

As with any type of electronics equipment, the actual effectiveness of the AN/ARD-13 depends on the design characteristics, the installation details, the qualifications of the operator, and the quality of the maintenance performed. Design features may eliminate many problems; but within the design limits of the equipment, maintenance and calibration determine its actual effectiveness. The maintenance practices and procedures, as prescribed in the appropriate technical manuals for the equipment and for the aircraft in which it is installed, must be adhered to.

CALIBRATION

The radiofrequency field pattern in the vicinity of the aircraft is distorted by the configuration of the aircraft itself. This distortion varies with respect to the earth's magnetic field, with the heading of the aircraft, and with the electromagnetic fields resulting from the operation of various equipment.

Although it is possible to compensate for many factors while on the ground, the final calibrations should be done in the air. It must be repeated when the operating area of the aircraft is changed. The procedure is elaborate and time consuming, but it is essential if the full value of the equipment is to be realized. For details concerning the calibration procedure, consult the appropriate volume of the Maintenance Instructions Manual for the specific model aircraft.

OTHER ADF EQUIPMENTS

AN/ARN-41A Direction Finder

Radio Receiving Set AN/ARN-41A is a combination automatic direction finder and radio receiver designed for use in aircraft. When signals from the sense antenna alone are selected, the equipment functions as a conventional radio receiver for continuous-wave and amplitude-modulated signals. When signals are selected from both the loop and sense antennas, the equipment functions as an automatic direction finder (ADF), providing automatic visual and aural indications of the relative direction from which radio signals are being received. The equipment frequency range is from 190 kHz through 430 kHz and from 480 kHz through 1,725 kHz. This is covered in three bands. The equipment may be used as an ADF or radio receiver on all its bands.

The AN/ARN-41A can be used for homing on a single station, or for triangulation position fixing using two or more stations, or for position fixing on a single station using any of the double bearing methods presently in use. Only ground waves of the transmitting station are used in ADF operation.

AN/ARA-25 UHF Direction Finder

The AN/ARA-25 is an ultrahigh frequency ADF that is used on most naval aircraft having UHF transceivers.

Desirable performance of the AN/ARA-25 and its relative freedom from serious maintenance problems, have proven it to be a reliable homing equipment. Accurate bearings on received signals at relative bearings of 000° and 180° are rapidly obtained; and while this is being accomplished, communication with the UHF Station is interrupted for only short periods of time. Bearings at other than 000° or 180° relative are not as accurate due to deviation.

The heart of the AN/ARA-25 ADF is the directional antenna. Because of the design of the antenna, no sense antenna is necessary. The AN/ARA-25 antenna is a flat, diamond-shaped (rhombic) plate placed over a tapered cavity. The cavity is designed to maintain a 50-ohm characteristic impedance at frequencies in the range of 225 MHz to 400 MHz.

BENCH TEST AND ALINEMENT

To either bench test or aline an ADF, the first consideration is whether the particular set is a complete receiver or an auxiliary piece of equipment. If it is an auxiliary equipment such as

13697

the AN/ARA-25 or AN/ARA-50, it must be placed in a bench set with the parent equipment. The parent equipment usually supplies the auxiliary with its power needs.

Normally there is no special test equipment needed that is peculiar to the ADF. Therefore, the important aspects of test equipment selection is the operating frequency of the ADF and test equipment, the type of modulation used by the ADF and test equipment, and the output signal of the particular ADF.

DOPPLER NAVIGATION SYSTEMS

Doppler navigational radar automatically and continuously computes and displays groundspeed and drift angle of an aircraft in flight without the aid of ground stations, wind estimates, or true airspeed data. This is done by utilizing auxiliary inputs from an altitude rate sensor and from the aircraft's vertical reference system. The Doppler navigation radar section does not sense range and bearing (direction) as ordinary search radar does. It employs continuous carrier wave transmission energy and determines the forward and lateral velocity components of the aircraft by utilizing the apparent frequency change phenomenon (Doppler shift) in the RF range.

The radar emits CW energy at one frequency; these waves of energy strike earth's surface and are reflected. Energy waves returning appear to be spaced differently than the waves that were transmitted.

The receiver of the Doppler radar system detects this apparent change in frequency; this is accomplished by use of two signal inputs–one from the transmitter and one from the receiver antenna. The input signal from the transmitter is at all times the same frequency as the signal being radiated; the receiver antenna signal frequency will vary with the relative speed. The two frequencies are compared in the receiver, and the difference frequency is a direct indication of the groundspeed of the aircraft.

An analysis of the Doppler shift, as it applies to RF frequencies, is presented in chapter 9 of this manual. Review of that material should prove helpful in understanding the discussions of actual Doppler radar navigational equipment.

TWO-BEAM SYSTEM (AN/APN-122)

One type of airborne Doppler navigation equipment is the AN/APN-122, an all-weather, self-contained system. It radiates two narrow, fixed beams of CW energy downward, outward, and rearward (thus the ground becomes an opening target) from the aircraft's longitudinal axis. The ground-returned energy is intercepted by the receiver and compared with the outgoing transmitter energy. The difference (due to the Doppler effect) is used to develop velocity component information for use in the computing section. The velocity component, with the aid of roll angle, pitch angle, and altitude rate data furnished from auxiliary equipment, derives the groundspeed and drift angle in the computing section.

The groundspeed and drift angle information is continuously displayed on an indicating dial. It is also made available as a continuous synchro output signal for tie-in with other navigational equipment–position computers, bomb directors, and/or integrated flight director systems.

Operating Principles

The receiver-transmitter unit, shown in figure 17-23, consists of a Fiberglas paraboloid which contains a waveguide assembly, two crystal mixer assemblies, and a klystron oscillator assembly. The inner surface of the paraboloid is sprayed with a metallic reflecting material. As well as serving as a container for the various units, the paraboloid also serves as the transmitting and receiving antenna. The paraboloid is divided in the center by a wall called the septum, in which the waveguide is mounted.

The transmitting waveguide originates at the klystron and is a T-shaped section terminating in two transmitting horns (only one transmitting horn is visible in figure 17-23). Two receiving waveguide sections are attached to the transmitting section. They have crystal mixer cavities mounted at the upper ends, receiving horns at the lower ends, and coupling slots provided between each receiving and transmitting section.

The klystron, mounted at the center of the waveguide, receives d-c filament and cathode power from the high voltage power supply and

13698

AT.326

Figure 17-23.–Receiver-transmitter unit, mechanical assembly.

13638
13699

liquid coolant from the electron tube liquid cooler. The klystron is a dual cavity resonator. The CW energy from the klystron cavity is coupled to the waveguide through an impedance matching aperture located in the end of the waveguide, and through a coupling choke built into the waveguide flange. The energy is coupled down through the waveguide to the T-section where a power divider sends half of the energy to each transmitting horn. The power divider is a small probe located across the waveguide at the center of the T-section.

The reflecting surface of the antenna dish concentrates the energy into two narrow beams on opposite sides of the aircraft. These beams are directed outboard and downward to the rear of the aircraft, as shown in figure 17-24. The beams are directed outboard from the aircraft through an angle of 11°; simultaneously, they are directed aft through an angle of 22°.

Although the angular width of the radar beam is narrow, its linear width increases with increasing distance from the aircraft. As a consequence, the angle of incidence of different parts of the beam and the direction of the energy reflected from the ground vary. Specifically, the result is that the energy striking the ground at the steepest angle relative to the longitudinal axis of the aircraft returns at the highest frequency, producing the lowest Doppler frequency; and the energy striking the ground at the flattest angle returns at the lowest frequency, producing the highest Doppler frequency. There will be a general frequency band or spectrum between these two Doppler frequency extremes, and the energy transmitted at the center and received from the center of the radiation lobe will be at the greatest power and at approximately the center frequency of this band.

The reflected energy is picked up by the receiving half of the antenna and focused into the receiving horns. This energy is directed through the waveguides to the receiving crystal mixer cavities. The impedance of the waveguide is matched to the crystal mixer by a matching aperture located at the coupling flange. The flange also contains a coupling choke to prevent loss of energy at this junction. A sampling of the transmitter's energy leaks into the receiving waveguides through two narrow coupling slots between the two sections of the

Figure 17-24.–Radar beam orientation.

transmitting and receiving waveguides. (See fig. 17-23.) These coupling apertures attenuate the transmitted energy so that only a small portion of its power is supplied to the receiving waveguide.

The crystal is placed across the cavity at a voltage point, as shown in figure 17-25, and functions as a pickup probe and as a mixer. Both the transmitted and received signals appear across the crystal; and since it is a nonlinear device, mixing action results. The sum and difference, and each of the two output frequencies, appear across the output of the crystal, but the sum and the two input frequencies are

13700

AT.328

Figure 17-25.–Crystal mixer assembly.

shunted to ground by the capacities formed by the vinyl insulating washers supporting the crystal at its output end. The output from each crystal mixer is a Doppler frequency proportional to the velocity along its respective beam (port or starboard). (See fig. 17-26 (A).) If the aircraft is drifting in the port direction (fig. 17-26 (B)), the Doppler frequency output of the port crystal mixer will be lower than the output of the starboard crystal mixer. If the aircraft drifts toward starboard, the output of the starboard mixer will be lower. The difference or Doppler frequency is within the audio spectrum.

Equipment Theory

Figure 17-27 shows a simplified block diagram of the AN/APN-122 system. The receiver-transmitter unit operation was discussed previously. The audiofrequency Doppler shift signal is coupled from each crystal to the amplifier assembly.

The port and starboard signals are amplified by separate channels and then routed to the signal data converter. As soon as satisfactory acquisition is made of the center Doppler frequencies in the search mode, the circuitry automatically switches to the track mode. Two voltages are produced–analogs of the center Doppler frequency of each channel (port and starboard)–and represent the velocity component of aircraft motion measured in the direction of the two radiation beams. (The average signal represents the velocity along the fore and aft axis, while the difference between the two signals represents the side to side velocity.)

A memory circuit is included to maintain track in the event of momentary loss of signal. The analog voltages are routed to an electromechanical analog computer. The computer converts the signals (which are proportional to the aircraft's velocity components relative to the radar beams) into potentials representative of the heading and drift velocity components of the aircraft. The resultant groundspeed and drift angle information is displayed on an appropriate indicator.

FIXED-WING SYSTEM (AN/APN-153)

The AN/APN-153(V) is a lightweight, miniaturized groundspeed and drift angle measuring system which is designed to satisfy the navigational requirements of modern military fixed-wing aircraft. It uses Doppler pulsed radar techniques to measure groundspeed and drift angle directly, continuously, and accurately. It operates anywhere, is relatively unaffected by weather conditions, and is independent of ground-based navigational aids. Its small size and light weight permit it to be easily installed in almost any fixed-wing aircraft.

The radar's groundspeed and drift angle data, together with aircraft heading data from any standard compass, are used to compute an aircraft's track projected on the ground. Using this information and conventional dead reckoning techniques, a pilot can navigate accurately over long distances.

Application

Groundspeed and drift data, in addition to being presented on a counter and dial, are available as electrical outputs. These outputs

can be fed automatically and continuously to navigational computers, mapping cameras, search radars, or other equipment which ordinarily utilize manual inputs of equivalent information.

A particularly useful application of the AN/APN-153(V) is its interconnection with various dead reckoning navigational computers, such as the AN/ASA-13A. Without the aid of a groundspeed and drift angle measuring system, navigational computers are sharply limited by the accuracy of the input information. The input data may consist of windspeed and direction, true airspeed, and aircraft heading. Only aircraft heading is usually obtainable with any high degree of accuracy.

Interconnection with this type of computer provides an automatic navigator which presents the aircraft's position with extreme accuracy. It is not limited by the accuracy of either available wind information or true airspeed data. The groundspeed and the drift angle are measured data and include the effect of wind. Thus, during normal operation, groundspeed and drift angle data need only be supplemented by aircraft heading data for continuous and automatic computation of the aircraft's position (given certain initial conditions).

Operating Principles

The AN/APN-153(V) emits short pulses of microwave energy, so the transmitter is not operative while an echo is being received. Therefore, in a single-beam radiation pattern there would be no second frequency with which

13703

to compare the echo. However, two beams—one projected dead ahead and the other directly behind—would experience equal but opposite Doppler shifts. In this event, one-half the difference between the two echo frequencies is the Doppler shift of either beam, and is proportional to groundspeed. This condition assumes no drift. If drift were present, the two-beam system described above would not detect it when used with pulsed beams. Antennas radiating to the left and right would detect sideways motion, but not fore and aft motion.

In order to make simultaneous measurement of both groundspeed and drift angle, the AN/APN-153(V) uses a modification of the two-beam pattern. The vicinity of the aircraft is divided into four quadrants—left forward, left rearward, right rearward, and right forward. (See fig. 17-28(A).) Simultaneous beams are radiated into diagonal quadrants, with switching of the quadrants at regular intervals.

When there is no drift, the ground track and aircraft heading coincide. In this condition, as shown in (B) of figure 17-28, the radiation pattern is symmetrical about the axes of the aircraft, and the left and right beams are at the same angle from ground track. The Doppler shift is equal in the beams.

When the antenna is not alined with ground track (fig. 17-28(C)), an angle exists between the antenna axis and ground track, and the beams experience unequal shifts. The difference frequency resulting from one pair of beams is higher than that from the other. As the switching action occurs, this difference is processed as an error signal which, through servo action, drives the antenna into alinement with ground track.

When the antenna is alined with ground track, the angle between the antenna axis and the aircraft heading represents the drift angle. Through a synchro system, this information is supplied to the computer along with the groundspeed data.

Advantages and Disadvantages

Due to its special radiation pattern, the AN/APN-153(V) is not affected by the vertical component of velocity which occurs during ascending or descending flight. Changes of altitude affect each beam equally, so the difference frequency remains the same. It is the difference frequency which is utilized to represent velocity.

Small roll and pitch angles of the antenna exist during normal flight. Roll angles introduce a greater shift into one beam and a smaller shift into the other, but the difference frequency is changed only slightly. Therefore, the inaccuracy of groundspeed measurements resulting from roll variations is very slight. Pitch angles do, however, cause inaccuracies which are significant. Therefore, the antenna is stabilized in its pitch axis to minimize pitch errors.

ROTARY-WING SYSTEM (AN/APN-130(V))

The AN/APN-130(V) is a four-beam navigation set which provides information for use in helicopter automatic navigation, as well as control during hovering and directional flight. This equipment is a representative advanced Doppler equipment used for measuring ground velocity components of helicopters and other air vehicles having hovering and negative speed capabilities. The set incorporates an antenna design featuring narrow beam widths, low sea effect errors, fully automatic navigate-hover transition, and automatic frequency trackers.

Operating Principles

The set employs four narrow beams of continuous-wave energy directed downward and outward, fore and aft, and in symmetrical configuration with respect to the aircraft, as shown in figure 17-29. Frequency shifts occurring in each beam are proportional to the components of aircraft velocity along the respective antenna beam. The frequency shifts, which are due to the Doppler effect, are detected by mixing a portion of the transmitting signal with the received signal and detecting the audio beat frequency.

After detection, the continuous Doppler audio signals are amplified and supplied to the signal data converter which converts the signals into voltages proportional to the aircraft heading velocity, drift velocity and vertical velocity. Outputs proportional to these voltages are provided in proper electrical form to drive the appropriate auxiliary equipment.

13704

AT.331

Figure 17-28.–Four beam pattern, using two-beam transmission.

Equipment Theory

The klystron tube in the radar receiver-transmitter generates continuous-wave RF energy at a frequency of 13.3 GHz± 5 MHz with a minimum power of 4.5 watts. The RF energy is coupled into the four transmitting wave guides and transmitted toward the earth in four narrow beams. A small portion of the transmitted energy is coupled into each pair of receiving waveguides through directional coupling slots spaced (electrically) 180° apart. (See fig. 17-30.) A portion of the transmitted energy is reflected from the earth to a parabolic reflector and into the four receiving horns. The RF energy for each beam is divided and coupled into two receiving waveguides for each beam. At this point, the two received

13705

UNIT VI - DIMENSIONING

How to Draw Arrowheads — Lesson 1

OBJECTIVE: To learn how to properly draw arrowheads.

RELATED INFORMATION:

When properly drawn, arrowheads can enhance the appearance of a drawing appreciably but when done sloppily, they can ruin an otherwise good drawing. Prospective employers attach great importance to a clean, neat drawing.

FIG. 1

FIG. 2

Arrowheads can be drawn freehand, making the sides either in one stroke, or in two strokes toward the point, as shown enlarged in Fig. 1. Most employers, however, prefer the solid-head type as shown in Fig. 2. This head is usually made thinner and longer than the open-head type and has very little curvature to the sides. It is made in one stroke and then filled if necessary. A good rule to remember is that the bases of arrowheads should not be made wider than one-third the length. Attempt to make all arrowheads on the same drawing the same type, open or solid, and the same approximate size, except in unususual cases. Depending on the drawing size, arrowheads will vary somewhat, but a good general rule to remember is that $\frac{1}{8}$ inch is a good length, and $\frac{3}{16}$ inch for larger drawings. Remember once more that poor arrowheads can ruin the appearance of an otherwise excellent drawing.

QUESTIONS:

1. What approximate size should arrowheads be drawn?

2. Are arrowheads drawn freehand?

AT.332

Figure 17-29.–Antenna beam orientation.

signals for each beam are designated A and B. The configuration of the A and B channel waveguides is such that the A signal is shifted 1/4 wavelength or 90° from the B signal. The eight received signals are heterodyned with the transmitted signal at the crystal detectors. The eight low-level Doppler signals are fed to the amplifiers where they are amplified to a sufficient level for transmission to the signal data converter.

Four pairs of signal channels in the signal data converter receive the corresponding pairs of quadrature signals from the audio amplifier subassemblies of the radar receiver-transmitter. Each pair of signal channels corresponds to one of the four antenna beams. (See fig. 17-31.)

The signal data converter provides two basic modes of operation–hover and navigate. Transition between these two modes is automatic when the HOV/AUTO switch on the control-indicator is in the AUTO position. In the HOV position, all channels of the signal data converter are locked in the HOVER mode of operation. In the AUTO position, each channel pair is switched to either the HOVER or the OMNIDIRECTIONAL NAVIGATE mode independently of the other channels, or all channels may be switched simultaneously to the FORWARD NAVIGATE mode. The switching is controlled by the signal-to-noise density ratio and the frequency of the Doppler signal in each channel. A fail-save feature is provided wherein each channel is automatically switched from either of the navigate modes in the event that the Doppler signal is lost for a period exceeding approximately 2 seconds.

In fixed-wing aircraft, forward flight can be assumed. This is not logical in aircraft capable of negative velocities. Rapid direction sensing, as well as accurate velocity measurement, is extremely important for helicopter maneuvers at low velocities and during operations requiring hovering. The hover mode then requires coherent counting. Coherent counting, as used in this application, refers to the method used to develop an analog d-c output signal whose amplitude is proportional to aircraft velocity and whose polarity is an indication of aircraft direction. The Doppler signal in itself is not an indication of aircraft direction.

It is safe to assume that when a helicopter is traveling at some high rate of speed, the direction of flight is limited to forward flight with limited drift angle. Under these conditions, it is not necessary that each counter sense aircraft direction; therefore, the counters may operate in the noncoherent mode as long as the output polarities have been correctly established in velocity-sensing circuits.

ASSOCIATED EQUIPMENT

As mentioned previously, Doppler navigational radar equipment by itself cannot determine aircraft position or navigate the aircraft to a predetermined point. However, when used with associated navigational computers, these operations can be accomplished. The major function of the Doppler equipment is to supply extremely accurate data concerning velocity and drift angle.

Although there are many airborne navigational computers in use at the present time (and

13706

AT.333

Figure 17-30.–Waveguide subassembly, receiver-transmitter coupling.

more are being introduced each year), a brief discussion of the AN/ASA-13A and its plotting board OA-1768/ASA will illustrate the overall system.

The AN/ASA-13A

Navigational Computer Group AN/ASA-13A is an airborne dead reckoning computer which continuously determines displacement from an initial reference. Displacement is computed in E-W and N-S coordinates from information obtained from within the aircraft. These coordinates, in the form of d-c voltages, are used to displace CRT sweep origins for ground stabilized PPI displays.

The computer (fig. 17-32) resolves and combines voltages representing the airspeed and wind vectors. The resultant ground velocity (in component form) is then integrated to

13707

AT.334

Figure 17-31.–Functional block diagram.

provide an indication of N-S and E-W ground displacement (distance) from an initial reference point. Inputs of magnetic heading and pitot pressure are automatically and continuously supplied from aircraft instruments. By manually inserting local variation, magnetic heading is changed to true heading. Pitot pressure is converted to airspeed data. The airspeed vector, defined by airspeed and true heading, is resolved into N-S and E-W components. The wind vector is similarly resolved and combined with the components of airspeed to provide ground track data.

The wind vector may be obtained from the Doppler radar system (when operating) or from the Doppler radar's memory circuit (when not tracking), or it may be manually inserted when the Doppler radar is not operating.

The OA-1768/ASA-13

Display-Plotting Board Group OA-1768/ASA-13 is a short-range airborne navigational device used to display ground track of the aircraft and target position data. It is used in conjunction with the AN/ASA-13 or -13A and a search radar system to provide a readily available view of the overall tactical situation. It is used during ASW or AEW maneuvers to provide an accurate reference on which to base tactical decisions.

The plotting board may be used to indicate as well as record the following:

1. The position of the aircraft with respect to a preselected origin.
2. The position of a target relative to a remote reference point.
3. The present position of the aircraft and its position relative to the target.

The display, in the form of an illuminated arrow (called the crab), is continuously oriented to correspond to aircraft heading and ground track. The crab is driven by servomechanisms in response to N-S and E-W data supplied by the navigational computer.

13708

AT.335

Figure 17-32.–AN/ASA-13A, block diagram.

INERTIAL NAVIGATION

The introduction into the fleet of aircraft with inertial navigation systems (INS) has created a whole new set of problems for the maintenance technician, and emphasized some of the older problems. The use of INS has required increased utilization of gyros, accelerometers, synchros, servos, and other mechanical devices. It has also resulted in increased utilization of analog computers. When integrated with other equipment to provide a complete tactical system, it has also required the increased utilization of the digital computer. These individual topics have been discussed separately in previous chapters of this course. The remaining section of this chapter illustrates the combination of these components to form an inertial navigation system and indicates how the INS is utilized to provide data for inclusion into a complete tactical system.

BASIC THEORY

Inertial navigation is a type of dead reckoning. Equipments presently in use have very good accuracy, and this accuracy is being constantly improved through improvement of components and alinement techniques. Instead of measuring speed directly, the system derives it from measurement of the vehicle's accelerations. Two accelerometers are required–one referenced to north, the other referenced east. The accelerometers are mounted on a gyrostabilized unit (called the stable platform) to avert the introduction of errors resulting from the acceleration due to gravity.

Initial conditions are set into the system, and the navigation process is begun. The accelerometers sense accelerations in the N-S and E-W directions. These accelerations are doubly integrated with respect to time, and changes are continuously made to aircraft positional data.

13709

NOTE: Integration and differentiation are specific types of mathematical computations, and are discussed in Mathematics, Vol. 2, NavPers 10071-B. In general, differentiation consists of breaking a relationship into small increments, while integration consists of combining increments into a larger idea. For example, in the relationship of acceleration, velocity, and distance, acceleration is a change in velocity per unit of time. Acceleration must be integrated with time (average acceleration multiplied by the time through which the acceleration is effective) to obtain the change in velocity. "Double integration" means that the first integral (velocity) must be integrated with time to form the second integral (distance).

STABLE PLATFORM

The stable platform (fig. 17-33) is attached to the vehicle through a gimbal system which permits it to assume any orientation with respect to the vehicle. In this typical system, three gyros are used, with their sensitive axes mutually perpendicular. The X-axis is oriented north and south, the Y-axis is oriented east and west, and the Z-axis is oriented perpendicular to both the other axes and in line with the earth's radius. Positive directions along the axes are defined as north, east, and toward the center of the earth. This terminology has been well standardized in all INS equipments.

Each gyro senses angular rate of displacement about its sensitive axis and precesses in accordance with the rate of displacement (as discussed in chapter 9 of this manual). It uses a pickoff unit to detect the precession in each axis and, through a servoloop, to drive a platform control torquer to null out the sensed rate and keep the platform "space stabilized" while the vehicle maneuvers about it. An additional correction is required to stabilize the platform with relation to the earth in order to eliminate errors of gravity. The method of compensating for this error is not discussed in this manual.

Displacement

As discussed in chapter 5 of this manual, motion of a body may be caused by either of two types of forces–contact forces or field forces. It is important to note that an accelerometer cannot distinguish between these forces. Newton's second law of motion describes acceleration force as follows:

The acceleration of a body is directly proportional to the magnitude of the applied force and inversely proportional to the mass of the body; acceleration is in the direction of the applied force.

It should be understood that the accelerometer will provide no output while it is moving at a constant velocity and its sensitive axis is perpendicular to the gravitational force. If the sensitive axis should become misalined, gravitational acceleration will result in a force which displaces the mass, causing the accelerometer to give an erroneous indicationof the vehicle's acceleration.

INITIALIZATION

In inertial navigation, the term initialization is used to denote the process of bringing the system to a set of initial conditions from which it can proceed with the navigation process. These conditions include leveling the platform, alining the azimuth reference, setting the initial velocity, setting the initial position, and making any computations required to start the navigation.

Failure to achieve the proper initial conditions is disastrous to navigational accuracy. Although all inertial navigation systems must be initialized, the procedure varies according to the equipment, the type aircraft in which it is installed, and whether the system is shore based or ship based. Initialization must be accomplished with great care and accuracy, and in strict accordance with prescribed procedures. These procedures are detailed in appropriate technical manuals.

INERTIAL NAVIGATION SYSTEM AN/ASN-36

The Inertial Navigation System AN/ASN-36 (INS) measures aircraft velocities in the north-south, east-west, and vertical directions. Aircraft pitch and roll data are furnished to associated flight systems and instruments for navigational computations and displays. Magnetic heading, true heading, heading error, and magnetic variation data are also generated and supplied. Indications of aircraft latitude and local

13710

13711

magnetic variation are continuously displayed by the associated computer-indicator group.

Figure 17-34 comprises a simplified system block diagram of the AN/ASN-36 INS, showing inputs, outputs, and interconnecting signal paths.

In the normal INS operating mode, the navigation problem is continuously solved. Thus, aircraft true heading attitude (pitch and roll), and velocity data are provided continuously as INS outputs. Linear velocities of the aircraft relative to earth are obtained by intergration of the linear aircraft accelerations measured by the accelerometers.

To isolate these measurements from the effects of gravity accelerations, the system accelerometers are continuously maintained alined to earth-referenced spatial coordinates. This requires that the three accelerometers are mounted at right angles on the platform, and that the platform be maintained continuously perpendicular to the local gravity and alined in azimuth to true north. In the horizontal plane, sensed values of N-S and E-W accelerations are integrated, becoming linear velocities along these axes. Since the platform is maintained stable, aircraft heading and attitude angles are referenced to the platform. Synchro transmitters provide INS electrical outputs which represent these angles.

Two gyros and three accelerometers are mounted on the platform. Each gyro has two degrees of freedom. The gyro and accelerometer outputs are amplified and applied to the platform computer where they are summed and integrated. The aircraft velocities obtained by integration are used for computing the present aircraft position in terms of latitude and longitude. They are also summed with correction signals to develop gyro torquing signals to maintain the platform level.

AT.337

Figure 17-34.–AN/ASN-36 INS, simplified system block diagram.

13712

The gyros sense displacement of the platform's coordinate axes. Gyro outputs (precession signals) are applied to three servoloops whose outputs are converted into aircraft roll, pitch, and heading error signals, which are used to maintain the platform's initial orientation.

Synchro transmitters on the platform gimbals indicate aircraft attitude in the three axes, and their signals are processed and applied to other aircraft systems.

Operating Modes

The INS operates in several navigational modes. Inertial-Doppler is the normal mode; the others are provided for tactical reasons or to permit uninterrupted operation in the event of failure of other associated equipments.

INERTIAL-DOPPLER MODE.–In this mode, the INS outputs are relative velocities along the X and Y axes, aircraft pitch and roll, true heading, and magnetic heading. The relative velocities are used by the computer-indicator group in generating acceleration and gyro torquing correction signals for the INS. Doppler-derived signals (from Doppler velocity-sensing radar such as the AN/APN 153(V)) are also used in computing these correction signals, thereby improving the overall system accuracy.

INERTIAL MODE.–In this mode, the computer-indicator group presents position and correction data from the velocities furnished by the INS. Absence of Doppler-derived velocity information adversely affects system accuracy.

DOPPLER MODE.–In this mode, heading and attitude data are inertially derived in the same manner as in the inertial-Doppler mode. The computer-indicator group uses only Doppler velocities for computing present position. The correction signals are derived from Doppler data.

AIR DATA MODE.–In this mode, true heading output signals are provided by adding the flux valve and manually inserted magnetic variation angles. Attitude information may be derived from the INS. Only air data velocities are used for computing present positions.

C-I GROUP OFF MODE.–When the computer-indicator group is turned off, acceleration and gyro torquing correction are not supplied to the INS. Acceleration correction signals are generated within the platform computer by inertially derived quantities. Although there is some sacrifice in accuracy, the INS continues to function as an attitude reference, and supplies pitch, roll, magnetic heading, and true heading data to other aircraft systems. It also computes and displays (on its control unit) accurate latitude information.

ASSOCIATED EQUIPMENTS

In AEW aircraft such as the E-2A, the AN/ASN-36 inertial navigation system comprises a portion of the overall Doppler-inertial navigation system used to provide accurate velocity, attitude, and heading data. These data are then used in the digital data processing system, the AN/ASA-27 control-indicator group, for computing the aircraft's present position.

The INS is used in conjunction with a Doppler velocity-sensing radar such as the AN/APN-153(V). When used in combination, the overall system accuracy is greatly improved by making use of the outstanding features of each system to compensate for the weaknesses of the other.

In most INS systems, the aircraft compass system and pitot pressure system are used (or at least made available for use) in the event of nonoperation of portions of the INS.

OTHER INS SYSTEMS

The AN/ASN-31

Basically, the theories of operation of the AN/ASN-31 and the AN/ASN-36 systems are similar, although aircraft missions are different, and some differences do exist in details of operation. The AN/ASN-31 INS is used in model A-6A attack weapon system to provide velocity, attitude, and heading information to the AN/ASQ-61 ballistics computer set, which computes present aircraft position. Several modules are interchangeable between the two equipments.

13713

The AN/ASN-31 has provisions for switching from a navigation coordinate system referenced to true north to a system referenced to grid north when the aircraft is flying inside the polar region (inside 70° latitude north or south). Grid north is a line parallel to the line of longitude which was used for initial INS alinement. The AN/ASN-36 does not possess this feature.

The LN-12

This INS is a small, compact, lightweight system used in the F-4B high speed intercept fighter. It is used in conjunction with the AN/ASN-46 navigation computer set, which computes the great circle (shortest) route to the target or base using spherical trigonometry.

13714

CHAPTER 18

AIRBORNE RADAR

The term radar is used to describe electronic systems which are used to locate airborne or surface targets. A review of the introduction to radar in Basic Electronics, NavPers 10087-B, reveals that the word RADAR is an abbreviation for RAdio Detection and Ranging. In addition to indicating the presence of targets, radar may also be used to determine bearing, distance, elevation, speed, relative size, and identification. The accuracy of each use of radar is determined by several characteristics.

CHARACTERISTICS OF RADAR

RANGE

Radar measurement of range or distance is possible because of the fact that radiated RF energy travels through space in a straight line at a constant velocity. The straight path and constant speed are changed slightly when the RF waves enter the atmosphere and will vary with atmospheric and weather conditions. (This is discussed later in this chapter.)

Velocity

RF energy travels at the speed of light, about 186,000 statute miles (162,000 nautical miles) per second. This is 300,000,000 meters per second in the metric system. Radar timing is usually expressed in microseconds, and the velocity of radar waves is often given as 328 yards of 984 feet per microsecond.

One nautical mile is equal to approximately 6,080 feet. This means that it takes RF energy approximately 6.18 microseconds to travel 1 mile.

Range Measurement

The pulse type radar set determines range by measuring the elapsed time during which the emitted pulse travels to the target and returns. Since two-way travel is involved, a total time of 12.36 microseconds per nautical mile will elapse between the start of the pulse from the antenna and its return from a target. The range in nautical miles of any object can be found by measuring the time elapsing during a round trip of the radar pulse (in microseconds) and dividing this quantity by 12.36. In equation form, this is:

$$\text{Range} = \frac{\text{elapsed time}}{12.36}$$

MINIMUM RANGE.–The minimum range capability of a radar is determined by the time of the transmitter pulse, or pulse width (PW), plus the recovery time of the duplexer and the receiver. (For purposes of this explanation, recovery time may be considered as the time required for the receiver to become operative after the transmitter has fired.)

The minimum range in yards, at which a target can be detected, is equal to the PW plus the recovery time, divided by 2 and multiplied by 328 yards (328 yd/μsec.).
Stated in formula:

$$\text{Minimum range} = \frac{\text{PW + recovery time}}{2} \times 328 \text{ yd}$$

$$= (\text{PW + recovery time}) \times 164 \text{ yd}$$

13715

3. How many strokes may be used to draw the sides of the arrowhead?

4. Is there a standard method of drawing arrowheads?

5. How many different sizes of arrowheads would you use on a drawing?

ASSIGNMENT:

Draw a $\frac{1}{2}$-inch border all around the 8" x 11" buff drawing paper. Draw the practice plate shown below, being sure to use both open and solid types of arrowheads as shown.

1369

Targets closer than this range are not seen because the receiver is inoperative for the period of time necessary for a signal to travel this distance.

An increase in recovery time (bad TR tube in the duplexer) not only increases the minimum range, but also decreases the receiver sensitivity.

MAXIMUM RANGE.–The higher the frequency of a radar wave, the greater the attenuation (decrease in signal strength) due to weather effect. Gases and water vapor that make up the atmosphere absorb energy from the radiated pulse. Frequencies below 3,000 MHz are not appreciably attenuated under normal conditions, while frequencies above 10,000 MHz are highly attenuated. Attenuation of the transmitted pulse results in a decrease in the ability of the radar to produce usable echoes at long ranges. A usable echo may be defined roughly as the smallest signal which a receiver-indicator system is able to detect, amplify, and present so that the observer can visually distinguish it from the noise signals on the CRT.

At lower frequencies, higher transmitter power can be developed more easily. Also, there is greater refraction and diffraction (bending of the waves). Lower radar frequencies are therefore superior for extremely long-range search radar. The effect of atmospheric conditions on radar signals is discussed in more detail later in this chapter.

The maximum range of any radar depends upon transmitted power, pulse repetition frequency, and receiver sensitivity. The peak power of the transmitted pulse determines the maximum range that the pulse can travel to a target and return in usable echo strength. Sufficient time must be allowed between transmitted pulses for an echo to return from a target located at the maximum range (established by design) of the system.

The maximum range is sometimes extended and vertical coverage reduced by the trapping of the radar beam in a DUCT. A duct is created by abnormal weather conditions; further coverage on ducts is given later in this chapter.

AZIMUTH

The azimuth (bearing) of a target is its clockwise angular displacement in the horizontal plane with respect to true north as distinguished from magnetic north. This angle may be measured with respect to the heading of an aircraft containing the radar set; in this case, it is called relative bearing. The angle may be measured from true north, giving true bearing, if the installation contains azimuth stabilization equipment. The angle is measured by utilizing the directional characteristics of an unidirectional antenna, and determining the position of the antenna when the strongest echo is received from the target.

Radar antennas are constructed of radiating elements and reflectors, and some types use a director element to produce a narrow beam of energy in one direction. The pattern produced in this manner permits the beaming of maximum energy in a desired direction. The transmitting pattern of an antenna system is also its receiving pattern. An antenna can therefore be used to transmit energy, to receive echoes (reflected energy), or both.

RESOLUTION

The range resolution of a radar is the minimum resolvable separation in range of two targets of the same bearing. Range resolution is a function of the width of the transmitted pulse, the type and size of the targets, and the characteristics of the receiver and indicator. With a well-designed radar, sharply defined targets on the same bearing should be resolved if their ranges differ by the distance the pulse travels in one-half of the time of the pulse width (164 yards per microsecond of PW). If a radar set has a pulse width of 5 microseconds, the targets would have to be separated by more than 820 yards before they would appear as two pips on the scope.

The azimuth resolution is the ability to separate targets at the same range but on different bearings, and is a function of the antenna beam width and the range of the targets. Antenna beam width may be defined as the angular distance between the half-power points of an antenna's radiation pattern. (Half-power points are those points at which the transmitted power is one-half

13716

the maximum value of energy that is radiated along the lobe center.) Two targets at the same range, in order to be resolved as being two targets instead of one, must be separated by at least one beam width.

Strong multiple targets appearing as one target can often be resolved in azimuth and bearing by reducing the gain of the receiver until only the strongest portions of the echoes appear on the CRT.

ACCURACY

The accuracy of a radar is a measure of its ability to determine the correct range and bearing of a target. The degree of accuracy in azimuth is determined by the effective beam width and is improved as the beam width is narrowed. On a PPI scope the echo begins to appear when energy in the edge of the beam first strikes the target. The echo is strongest as the axis of the beam crosses the target, but the echo continues to appear on the scope as long as any part of the beam strikes the target. The target appears wider on the PPI than it actually is, and the relative accuracy of the presentation depends in a large measure on the width of the radar beam and range to the target.

The true range of a target is the actual distance between the target and the radar set (fig. 18-1). In airborne radar, the true range is often called SLANT RANGE. The term slant range is used to indicate that the range measurement includes the effect of difference in altitude.

AT.338

Figure 18-1.–Slant range versus horizontal range.

The horizontal range of a target is a straight line distance (fig. 18-1) along an imaginary arc parallel to the earth's surface. This concept is important to the radar observer because an airborne target, or the observer's aircraft, need only to travel the distance represented by its horizontal range to reach a position directly over its target. For example, an aircraft at a slant or true range of 10 miles, and at an altitude of 36,000 feet above the radar observer's aircraft, possesses a horizontal range of only 8 miles.

The timing sequence of a radar range indicating device starts at the same instant that the transmitter starts operation. Therefore, with airborne surface-search radar, the first targets seen are those directly beneath the aircraft. However, on the PPI scope, there is a hole in the middle of the picture (fig. 18-2), with a minimum radius corresponding to the altitude of the aircraft. In some systems the radius of the altitude ring will vary as the lower limit of the vertical radiation pattern is increased by raising the tilt of the radar antenna. Objects which are actually directly beneath the aircraft appear on the scope at a distance equal to the distance between the aircraft and ground. For greater accuracy of surface ranges, the relationship between the range of the target and the range of the altitude ring must be considered.

FACTORS AFFECTING RADAR

There are many factors, or elements (including atmospheric conditions), that affect radar performance. One of the principal factors is maintenance. The ability to keep the equipment operating at peak efficiency will influence the overall capabilities and limitations of the radar.

Another important factor is the radar operator's knowledge of the equipment. He must know the maximum and minimum ranges at which he can expect to pick up various targets, range and bearing accuracy of the gear, and range and bearing resolution. If the radar is a height finder, the operator must know the altitude determination accuracy and the altitude resolution. Information on these factors is con-

13717

tained in the Operation and Service Instruction Manual for each radar.

Peak Power

The peak power of a radar is its useful power. Range capabilities of the radar will increase with an increase in peak power. Doubling the peak power (a 3-db gain) will increase the range capabilities by about 25 percent.

Pulse Width

The longer the pulse width, the greater the range capabilities of the radar. This is due to the greater amount of RF energy sent out in each pulse. In addition, consider the fact that narrow bandpass receivers may be used, thus reducing noise level. An increase in pulse width, however, reduces the range resolution capabilities of the system.

AT.339

Figure 18-2.–Effect of altitude on radar. (A) Radar tilted down; (B) radar with zero tilt.

13718

Beam Width

The beam width is specified in degrees between the half-power points in the radiation pattern.

The effective beam width of a radar is not a constant quantity because it is affected by the receiver gain (sensitivity) and the size and range of the target.

The narrower the beam width, the greater the concentration of energy. The more concentrated the beam, the greater the range capabilities for a given amount of transmitted power.

Receiver Sensitivity

The sensitivity of a receiver is a measure of the ability of the receiver to amplify and make usable a very weak signal. The more sensitive the receiver, the greater the detection range of the radar. Sensitive receivers are easier to jam, however, and interference will show on the scope more easily.

Indicators

The choice of the type of scope used to display weak pips will add to the capabilities of the radar. The deflection-modulated A-scope is more sensitive to weak echoes than the intensity-modulated PPI. In some airborne installations that carry an oscilloscope for maintenance purposes, a weak target can be seen on the A-scope before it can be detected on the PPI.

Antenna Rotation

The more slowly the antenna rotates, the greater the detection range of the radar. Thus, an antenna which is not rotating would afford the greatest range in the direction it is pointing, within the limits of the radar. For tactical reasons, it is best not to stop the antenna from rotating and point the antenna beam at the target, except momentarily, and then only to gain information on composition of a target.

Atmospheric Conditions

The paths followed by microwave and VHF signals, whether direct or reflected, usually are slightly curved. The signals travel through the atmosphere at speeds that depend on temperature, atmospheric pressure, and the amount of water vapor present in the atmosphere. Generally, the higher the temperature the faster the signal; the lower the atmospheric pressure, the faster the signal; and the less the amount of water vapor present, the faster the signal. The net result of these influences is that the signal speed changes with altitude and, under normal atmospheric conditions, the variation is a small and uniform increase in the speed of the signal with increasing altitude. This causes all paths to curve slightly downward, as shown in figure 18-3, extending the radar horizon beyond a tangent to the earth. (See fig. 18-4.) The amount of the extension of the radar horizon varies with weather conditions. Under normal conditions, the radar horizon is extended 1.25 times the optical line of sight.

To understand the reason for this curving downward, imagine a surface called a wave front such as the one represented by line AB (fig. 18-3), where A is higher in altitude than B. A wave front is a surface, not necessarily flat, chosen in such a way that the phase of the signal is the same at all points on the surface. The signal always travels in a direction perpendicular to the wave front. Now, as wave front AB moves with the signal, it reaches position A'B' after a short time interval. The speed at A and A' is faster than the speed at B and B', since A and A' are at a greater altitude. Therefore, in a given time, the upper part of the wave front moves farther than the lower part, and the wave front tips slightly forward as it moves along. Since the path followed by the signal is always

AT.340

Figure 18-3.–Microwave path.

13719

AT.341

Figure 18-4.–Extension of radar horizon.

perpendicular to the wave front, it curves slightly downward as the wave front tips.

The bending of radio or radar waves due to a change in the density of the medium through which they are passing is termed refraction. The measure of the bending that occurs is indicated by the difference in index of refraction from one substance to another. The density of the atmosphere changes at a gradual and continuous rate; therefore, the index of refraction changes gradually with increased height.

The temperature and the moisture content of the atmosphere normally decrease with height above the surface of the earth. Under certain conditions, the temperature may first increase with height and then begin to decrease. Such a situation is called temperature inversion. More important, the moisture content may decrease more rapidly with height just above the sea. This effect is called moisture lapse.

Either temperature inversion or moisture lapse, alone or in combination, may produce a great change in the index of refraction of the lowest few hundred feet of the atmosphere, resulting in greater bending of the radar waves. This may greatly extend or reduce the radar horizon, depending on the direction in which the radar waves are bent. The height of the radar antenna with respect to the DUCT formed by this strange occurrence is of much importance.

Although duct conditions can happen any place in the world, the climate and weather in some areas make their occurrence more likely. In some parts of the world, particularly those having a monsoonal climate, variation in the degree of duct formation is mainly seasonal, and great changes from day to day may not take place. In other parts of the world, especially those in which low barometric pressure areas recur often, the extent of nonstandard propagation conditions varies considerably from day to day, even during the season when they are most common.

Sometimes, for various reasons in different areas, some upper level air becomes heated and often partially dried out. This effect is associated with clear weather rather than with storms. The temperature inversion and a layer of very dry air, which spreads out horizontally, create conditions favorable to the formation of a sky duct. The top of a duct can often be recognized by a thin layer of haze. The haze is a result of the moisture in the warm air condensing as the air starts to get colder.

The height and width of ducts can be predicted by the meteorological office. This is done by plotting temperature variations versus height. Figure 18-5 shows a standard variation chart compared with charts of nonstandard conditions.

TYPES OF AIRBORNE RADAR

The fundamental principles of all radar are similar; however, there are two basic types of radar systems–pulse and CW (continuous wave). FM radar is a type of CW radar. The Doppler principle can be used in both CW and pulse radars. The distinction between CW and pulse radar becomes less clear in systems where a combination of pulse and CW techniques is used. In general, a radar system is considered a pulse system when the RF energy is emitted less than 10 percent of the time. Most pulse radars emit energy less than 0.1 percent of the time. When the radar emits energy more than 10 percent of the time, it is classified as a CW radar system.

Most of the emphasis in radar development has been on pulse radar systems, primarily because of the rate at which information is collected, as compared to CW radar. However, there are specific applications in which CW radar performs more efficiently than pulse radar; for example, working to zero range and reduction of ground clutter.

Radar is a powerful aid to the aircraft, and the aircraft is an aid to the radar. The aircraft supplies an elevated platform to the radar, thereby extending the effective range at which objects can be detected. The application of radar to airborne operations has been most successful

13720

AT.342

Figure 18-5.–Height versus temperature. (A) Standard variation; (B) surface duct; (C) sky duct.

and airborne radar is an indispensable part of the Navy's fighting team. In naval aircraft, radar has many different uses, each requiring a different application of the fundamental principles.

SEARCH

Search radar, the basic type used in many radar-equipped aircraft, shows the range and azimuth of targets such as ships, islands, coastlines, and other aircraft within the reach of its beam. Search radar is an effective aid to air navigation since it exhibits land masses and storm clouds on the radar screen. In larger aircraft the IFF interrogation antenna is mounted on the search radar antenna in order to obtain IFF target bearing and range, which identifies ships and aircraft as friendly or hostile by means of coded replies.

Airborne search radar is generally classified as medium range and operates in either S-band or X-band. Figure 18-6 indicates the relative positions of the S-band and the X-band. The pulse width utilized by the radar is variable, depending on the range selected: on shorter ranges a narrow pulse width (0.5μsec.) is used; longer ranges may use a pulse width up to 5μ sec. The narrow pulse width permits a short

AT.343

Figure 18-6.–Electromagnetic energy spectrum.

13721
13720

minimum range, a high degree of range resolution, and greater range accuracy. The wide pulse width is used to aid in detecting small targets at greater distances.

The pulse repetition frequency (PRF) of the radar also usually varies with the ranges used– a high PRF is used on the shorter ranges for better target illumination, and a low PRF is used for obtaining greater maximum ranges.

HEIGHT FINDING

Height-finding radar is used to determine the altitude of a target by placing a narrow vertical beam on the target and measuring the position angle. The position angle is combined with the slant range to compute the altitude of the target above the horizontal. In airborne use the computed altitude of the target may be either the height above your aircraft or the height above ground. For computation of the target's altitude above ground, the altitude of your aircraft must be set in.

Another type of height-finding radar is the absolute altimeter. The absolute altimeter (radar altimeter) measures the distance from the aircraft to the ground or objects below. This is done by transmitting RF energy down, and receiving the reflected energy at the aircraft. In FM equipment the altitude is determined by the frequency difference between the reflected signal and the transmitter signal. In pulse equipment the altitude is determined by measuring the time required for the transmitted pulse to hit the ground and return. The indicating instrument will indicate the true altitude of the aircraft, which is its height above water, mountains, buildings, or other objects on the surface of the earth.

FIRE CONTROL

There are three basic types of fire control systems found in naval aviation. They are the day intercept system (visual), the all-weather intercept system, and the missile control system. (NOTE: For purpose of clarity, missile control systems are covered separately.) The day intercept system currently uses either of two types of automatic range only (ARO) radar.

One type uses a fixed antenna and furnishes range information to a computer group. The pilot, with the aid of the optical sight, aims his aircraft at the target. The radar then locks on the target and furnishes range information to the computer. Range may also be indicated on a meter or range indicator in the cockpit.

Another type of ARO radar has an antenna that scans in azimuth and indicates the heading and range to a target on a CRT. It also displays an artificial-horizon bar to aid the pilot in flying the aircraft. The search mode of this type radar provides range and direction information for use in maneuvering the aircraft to within visual attack range. Once visual contact is made, the antenna is locked in the dead ahead position and the attack is completed, using the optical system with the radar supplying range and range rate information to the computer.

The all-weather firecontrol system uses radar rather than optical means to search out a target. Once a target is found and selected, the radar tracks the target in range, elevation, and azimuth, and presents steering information on the flight indicator screen (CRT). This equipment may also provide a surface-search mode of operation. In the all-weather mode of operation, the computed lead angles are presented on the CRT. In the visual mode, the radar antenna is pointed dead ahead and the set functions as an ARO radar.

Missile Control

The radar used in the missile control system is essentially the same as that used in the all-weather system with the addition of a CW radar group. The CW radar is used to illuminate the target and usually shares the same antenna with the pulse radar. Since modern missiles utilizing CW radar carry their own computing circuits and determine their own flightpath, the CW radar can be a relatively simple system. In use, the target is detected and tracked with the pulse radar, while the CW radar illuminates the target with CW energy. The missile homes on this reflected CW energy.

NAVIGATION

Doppler navigational radar automatically and continuously computes and displays groundspeed and drift angle of an aircraft in flight without the aid of ground stations, wind estimates, or true airspeed data. This is done by

227 1373

utilizing auxiliary inputs from an altitude rate sensor and from the aircraft's vertical reference system. The radar section does not sense range and bearing (direction) as ordinary search radar does. Instead, it is speed-conscious and drift-conscious. It employs continuous carrier wave transmission energy and determines the forward and lateral velocity components of the aircraft by utilizing the principle known as Doppler effect.

The Doppler effect, or frequency change of a signal, can be explained in terms of an approaching and receding audio sound emitter. As shown in figure 18-7 (A), the sound emitter is on a moving ambulance and the receiver is the ear of a stationary listener. Assume that the frequency of the siren is 1,000 Hz.

Notice the spacing between the waves from the stationary emitter, as illustrated in figure 18-7 (B). If the emitter and listener were standing still, then 1,000 waves of sound energy would reach the listener in one second.

In figure 18-7 (C), the emitter is moving toward the listener (closing). The emitter moves a little closer to the listener between successive waves of energy, so each wave reaches the listener sooner than it would if the emitter were stationary. This means that the listener hears more than 1,000 waves of energy in one second, and consequently the sound is higher in pitch.

AT.344

Figure 18-7.–Doppler effect with sound waves.

The reverse is true in figure 18-7 (D). The emitter is moving away (opening), so the interval between successive waves is greater. Since the listener hears less than 1,000 waves in one second, the frequency of the emitter seems lower than it actually is.

Doppler radar employs the frequency change phenomenon just described, except in the RF frefrequency range.

The radar emits CW energy at one frequency, and these waves of energy strike the target and are reflected. Energy waves returning from the target are spaced differently than the waves striking the target. A closing target moves a little closer to the radar between successive waves, and reflects the waves sooner than if it were stationary. The closer-spaced waves mean that the frequency has increased slightly.

If the target moves toward the radar or if the radar moves toward the target faster, the waves of energy will be even closer together, causing a greater frequency change. The faster the closing speed, the higher will be the frequency of the returning waves.

The receiver of the Doppler radar system has two signal inputs–one from the transmitter, and one from the receiver antenna. The input signal from the transmitter is at all times the same frequency as the signal being radiated; the receiver antenna signal frequency will vary with the relative speed of the target and the radar. The two frequencies are compared in the receiver, and the difference frequency is a direct indication of the closing or opening speed of the target.

The Doppler effect is present any time there is relative motion (opening or closing distance) between the radar and the target. Therefore, the radar could be moving toward a stationary target and the effect would be the same as if a target moved toward a stationary radar.

One type of airborne Doppler navigation equipment is an all-weather, self-contained system. It radiates two narrow, fixed beams of CW energy downward, outward, and rearward (thus the ground becomes an opening target) from the aircraft's longitudinal axis. The ground-

SST 13723

returned energy is intercepted by the receiver and compared with the outgoing transmitter energy. The difference (due to the Doppler effect) is used to develop velocity component information for use in the computing section. The velocity component, with the aid of roll-angle, pitch-angle, altitude, and altitude-rate data furnished from auxiliary equipment, derives the ground-speed and drift angle in the computing section.

The groundspeed and drift angle information is continuously displayed on an indicating dial. It is also made available as a continuous synchro output signal for tie-in with other navigational equipment–position computers, bomb directors, and integrated flight director systems.

RADAR CIRCUIT THEORY

Radar equipments vary considerably in detail, depending on the amount of information and the accuracy of the data which they are required to supply. However, all radar systems using pulse modulation work on essentially the same principles, and their basic operations depend on the same kinds of major components. A basic radar system is shown in simplified block diagram form in figure 18-8.

SYNCHRONIZER

The synchronizer is the timing unit which is the heart of the entire system. It produces trigger pulses which control and coordinate the circuits of the system so that each operates at the correct time. In most systems it governs the number of pulses the transmitter produces in each second. It coordinates the sweep voltage (or current) to the indicator tube with the firing of the transmitter, and contains provisions for delaying the beginning of the sweep to give special types of display (such as open center and target discrimination operation). The synchronizer contains the circuits which generate the range marker voltages and the trigger pulses which unblank the indicator tube when the trace starts to appear on the screen. Pulses supplied by the synchronizer are also used to indirectly control the associated equipment used with the search system.

AT.345

Figure 18-8.–Block diagram of basic airborne radar system.

In some equipments the master trigger is synchronized with the aircraft's 400 Hz a-c power. The 115-volt a-c power input to the synchronizer (fig. 18-9) is connected to peaking choke L1. The output from the choke is a positive and a negative pulse at line frequency or 380 Hz to 420 Hz. The choke output is fed to a biased cathode follower, V1A. This tube is biased below cutoff; therefore, only the positive pulse is applied to the input of blocking oscillator V1B. The output (PRF) from the blocking oscillator is the same as the powerline frequency.

Eight output triggers are developed from the master trigger. Two of the output triggers are coincident with the master trigger. The other six triggers are delayed in delay lines. Taps are provided on the synchronizer delay lines for the following delays: one fixed at 15μsec., another fixed at 24 μ sec., two fixed at 30μ sec., and two jointly variable from 15 to 32μ sec. The variable delay is provided by switches and a relay. The relay is controlled by a remote switch at the operator's station and provides the modulator with a choice of two trigger delays for sonobuoy or search operation. This variable delay is adjustable by two coarse and two fine controls on the front of the synchronizer. Cathode followers provided low-impedance outputs for the triggers. The block diagram in figure 18-10 illustrates the sequence and use of the output triggers.

Some radar synchronizers utilize a multivibrator for the master oscillator. They normally contain switching provisions for changing the output frequency (PRF).

Figure 18-9.–Master trigger circuit.

MODULATOR

The modulator controls the operation of the transmitter by applying high-voltage pulses of rectangular shape. The pulses are usually supplied by charging a section of artificial transmission line in the modulator to a high potential during the interval between pulses. The modulator action begins when a trigger pulse from the synchronizer is applied to an electronic switch tube in the modulator unit. The switch tube terminates the artificial line and causes it to discharge a rectangular pulse through the transmitter tube. The length of time during which energy is transmitted is called the pulse width. In airborne applications, the modulator unit is usually enclosed in a container and operated under a constant pressure to prevent high-voltage arcing.

Figure 18-11 illustrates a block diagram of a modulator and high-voltage power supply.

Three-phase, 400 Hz power is supplied to the modulator through a variable power transformer (autotransformer or Variac). This transformer controls the amplitude of the high-voltage pulse to the magnetron by controlling the input voltage to the high-voltage rectifier.

The output from the high-voltage rectifier is applied through charging choke L1 to the series-resonant pulse forming network (PFN), Z1. Charging diodes hold the peak voltage on the PFN after the charge cycle is over.

To discharge the PFN, the thyratron switch tube is ionized by a trigger from the synchronizer. When the thyratron is ionized, it acts as a shorting switch on the input terminal of the PFN. The PFN is discharged through the primary of a transformer in the receiver-transmitter.

Inverse diode CR6 shunts the pulse forming network to damp out switching oscillations, and to shunt to ground any negative voltage appearing on the input terminal of the PFN caused by the magnetron or by waveguide arcing.

Blocking oscillator V2 increases the amplitude and shape of the positive input trigger from the electrical synchronizer for reliable triggering of the thyratron switch tube.

Cathode follower V3 isolates the blocking oscillator from the thyratron grid, which prevents oscillations that could cause multiple triggering.

TRANSMITTER

The transmitter consists principally of a magnetron which oscillates at extremely high frequency throughout the interval of the pulse applied by the modulator. The magnetron produces the electromagnetic energy which is

UNIT VI - DIMENSIONING

Drawing Figures — Lesson 2

OBJECTIVE: To learn how to properly draw and place figures including fractions.

$2\frac{1}{2}$ $\underbrace{2\frac{1}{2}\ 2\frac{1}{2}\ 2\,1/2\ 2\ \frac{1}{2}}_{\text{Avoid}}$

Correct

FIG. 1

RELATED INFORMATION:

Common fractions should be drawn with the fraction bar parallel to the guide lines of the figure, and with the numerator and denominator each somewhat smaller than the height of the whole number, so that the total fraction height is twice that of the integer (Fig. 1). Avoid the incorrect figures shown. Be sure to draw clearly, for a mistaken figure can cause numerous problems.

All figures should be so arranged as to be readable from the bottom or right side of the drawing only. This method enables the reader of the drawing to find the dimensions much more easily.

QUESTIONS:

1. Should the numerator be drawn smaller than the whole number?
2. Should the denominator be drawn smaller than the whole number?
3. Why be careful in drawing figures?
4. Should a figure be drawn so that it is readable from the left side of the drawing?
5. How can you improve your technique in drawing fractions?

ASSIGNMENT:

Lay a piece of tracing paper over the row of figures drawn below and trace all the figures.

$8\frac{3}{4}$ $3\frac{1}{4}$ $2\frac{1}{3}$ $5\frac{3}{4}$ $7\frac{1}{8}$ $6\frac{3}{8}$ $4\frac{1}{2}$ $5\frac{3}{4}$ $9\frac{5}{8}$

AT.347

13726

radiated from the antenna into space. Airborne radar sets employ microwaves, a typical value of wavelength being about 3 centimeters. The output of the magnetron is conducted to the antenna through waveguide transmission lines consisting of hollow metal tubing.

The high-voltage pulse section, which includes the magnetron, receives the high-voltage pulse from the modulator; the voltage is stepped up by pulse transformer T4. (See fig. 18-12.)

Pulse transformer T4 has two secondary windings of similar electrical characteristics, each connected to a filament lead of the magnetron. These two windings maintain an equal and in-phase voltage on each side of the filament when T4 receives the high-voltage pulse from the modulator. The electrical action of these windings, with associated capacitors, prevents the high-voltage pulses from appearing across the filament of the magnetron or the

AT.348

Figure 18-11.–Block diagram of modulator function.

13727

secondary of the magnetron filament transformer.

Each pulse drives the cathode of the magnetron negative. This causes the magnetron to oscillate for the duration of the pulse. These high-power pulses of RF energy are coupled into the waveguide section duplexer.

WAVEGUIDE AND DUPLEXER

The waveguide assembly (fig. 18-13 couples RF from the magnetron to the antenna for transmitting and the received echo from the antenna to the receiver.

All coupling between sections is accomplished by choke coupling. Choke coupling is accomplished by standard fittings designed to present low-impedance points at the junctions of the inside walls of the waveguide.

The transmitter and the receiver are effectively isolated from each other during each function by means of a load isolater and the duplexer assembly. The RF output from the magnetron is coupled to the duplexer through a section of waveguide that contains a ferrite load isolator.

The load isolator, W2, is a section of waveguide containing a ferrite element and a

AT.349

Figure 18-12.–Transmitter and associated circuits.

13728

permanent magnet. It allows power generated by the magnetron to be transmitted with very little loss, but will appear as a high-level attentuator to any reflected energy. This allows the magnetron to work into a matched load, thus providing very stable tube operation.

The RF energy from the load isolater enters the transmitter side the hybrid section of the duplexer. The high-level RF energy will excite TR tube V3 and ionize the gas contained therein. This ionized section will appear as a short across the waveguide, and the electrical characteristics of the hybrid will direct the reflected energy to the antenna side of the hybrid and thence to the output flange of the receiver-transmitter. Thus in the transmit condition, the

AT.350

Figure 18-13.–Waveguide assembly.

13729

duplexer prevents the high-level RF energy from entering the receiver portion of the waveguide and directs it toward the antenna.

ANTENNA

The RF energy from the transmitter is coupled to the antenna through several sections of waveguide, a directional coupler, and a waveguide switch.

The directional coupler is a section of waveguide that provides a fitting for attaching test equipment to measure the transmitter power output and the receiver sensitivity.

The waveguide switch is used to couple RF energy from the transmitter to the antenna assembly or to an electrical dummy load.

The antenna reflector focuses and directs RF energy generated by the radar transmitter and collects the RF energy reflected from targets. The antenna also provides azimuth information to the associated indicator groups by employing a servomechanism to transfer azimuth data.

The radiated beam of energy can be elevated or lowered to cover the desired areas by manipulation of the manual-tilt control on the antenna control. This changes the tilt angle of the reflector with respect to the aircraft's fuselage or to the true horizontal, depending on whether or not the radar has tilt stabilization incorporated. The true horizontal is determined by a gyro reference system.

Tilt Stabilization

Tilt stabilization is used to correct the tilt angle of the transmitted beam of RF energy to compensate for deviations in the attitude of the aircraft, thereby maintaining the beam throughout the scanning range at the angle selected by the tilt control on the antenna control. The stabilization range on one type of radar is such that, if the tilt control is set for 0°, the beam is maintained at this angle for aircraft pitch or roll up to ±30°. If the tilt control is set for other beam angles, these limits vary accordingly. A typical tilt-stabilization system is shown in figure 18-14.

The conditions depicted in figure 18-14 resulting in the waveform shown at the left, are as follows:

1. Aircraft is entering a climb.
2. Manual-tilt control is set for zero tilt.
3. Tilt-stabilizer mechanism is functioning in response to gyro signals.
4. Scanner's instantaneous position is "dead ahead."

NOTE: The amplitudes for waveforms 7 and 8 are not drawn to comparative scale.

The tilt-stabilization system shown in figure 18-14 consists of a gyroscope unit, a servoamplifier, the resolver synchro, manual-tilt synchro, tilt-torque motor, damping signal generator, and followup synchro. The gyroscope unit is separately mounted on the aircraft structure, and the resolver synchro and the servoamplifier are mounted on the antenna frame. The tilt-torque motor, damping-signal generator, and followup synchro are contained in the tilt-servo unit mounted on the rotary section of the antenna. The manual-tilt synchro is mounted on the antenna control box.

Stabilization is effected by the use of two signals: the resolver synchro signal, and the manual-tilt synchro signal. Separate pitch and roll signals originating in the gyroscope unit are combined in the resolver synchro to produce the single resolver-synchro signal. The manual-tilt synchro signal originates in the followup synchro and provides the tilt-stabilization system with continuous information as to the tilt angle of the reflector. This signal passes through the manual-tilt synchro in the antenna control where it is modified according to the setting of the tilt control. The resolver-synchro signal and the manual-tilt synchro signal, which differ in phase by 180°, are combined at the input of the servoamplifier, and the amplified resultant, or error signal, is used to control the tilt-torque motor in correcting the tilt angle of the reflector.

RECEIVER

The typical radar receiver is an extremely sensitive superheterodyne containing circuits with bandwidth capable of passing pulses of the type emitted by the transmitter. It is important that the receiver generate as little local noise voltage as possible to avoid masking weak echo signals.

In the receive condition, the magnetron is not being pulsed and the TR tube is not fired. Energy received by the antenna is directed to

13730

AT. 351

Figure 18-14.–Antenna tilt-stabilization servosystem.

13731

the receiver, where it enters the duplexer on the antenna side (fig. 18-13). This energy is at a very low power level; consequently, the TR tube will not fire and will appear as a continuous open waveguide. After traveling through the TR tube, the received energy enters the low-power hybrid section of the duplexer, which directs it to a crystal mixer. The electrical characteristics of the duplexer provide directivity in such a manner as to minimize received energy losses in the transmitter portion of the waveguide. Received energy is directed from the duplexer into the mixer where it is heterodyned with the output of the local oscillator (a reflex klystron) at the mixer crystals to produce the required IF of the receiver. The local oscillator is stabilized by an AFC system to keep the receiver intermediate frequency from drifting.

The IF output resulting from the mixing process is then amplified in a number of IF stages. In most aircraft radar receivers, the intermediate-frequency value is between 15 and 60 megahertz. A video detector converts the IF energy into video pulses. After passing through one or more stages of video amplification, the signals are applied to the cathode-ray indicator.

AFC System

A cross guide coupler, located on the transmitter arm of the waveguide, continuously couples a small portion of the transmitter output to a separate mixer in the receiver called the AFC mixer, to which some of the output of the klystron local oscillator is also applied. The AFC mixer develops the difference frequency of the two and applies this signal to a discriminator circuit. The disciminator output voltage is at a reference level when the correct intermediate frequency is produced. But if the receiver local oscillator attempts to drift off frequency, the discriminator produces a d-c voltage which is positive or negative from the reference level, depending on whether the local oscillator frequency is too high or too low. The d-c output of the discriminator is then applied through associated circuits to the repeller plate of the klystron local oscillator. This corrects the klystron frequency until it differs from the transmitted frequency to produce the correct IF.

IF Amplifier and AGC

The outputs of the receiver crystals in the mixer assembly are brought into the IF amplifier through coaxial lines. The IF amplifier of the receiver is a linear amplifier employing a changeover circuit, with an instantaneous automatic gain control (AGC) circuit. A relay provides the changeover from linear to COAC (clutter-operated anticlutter) when selected. Linear (LIN) operation of the receiver presents the target on the companion CRT at the true representative length and overall intensity. COAC causes the target to be presented on the indicator CRT with the leading edge of the target at normal intensity and the remainder of the target at reduced intensity. This feature allows a target to be seen which might otherwise be obscured by clutter (fig. 18-15). In LIN operation, only the land mass can be seen. However, the intensity of the land mass is reduced in COAC operation (except for the leading edge) and the otherwise obscured target can be seen.

AGC is a negative voltage applied to the suppressor grids of the IF amplifiers, except the first two and the last one, to reduce the receiver gain when signals of large amplitude and long duration are received. AGC is accomplished by detecting the negative portion of the IF pulse (fig. 18-16). The negative d-c pulses from the plate of V5 are filtered, coupled through the control relay K1 (when in COAC operation), and mixed with the manual GAIN control d-c voltage and sensitivity time control voltage (when STC is selected) on the grid of V6A.

The output is taken off the cathode of V6A and applied to RC network C3, R7 and C4. Due to the relatively long RC time constant of R7 and C3, the negative voltage pulse is not immediately applied to the AGC bus. CR1 does not conduct; it appears as a high resistance for the charge of C3. From the time the pulse starts (t1) until C3 is charged (t2), the receiver gain is essentially linear; that is, it operates with limited AGC. This allows the leading edge of any signal to be amplified at full gain before the AGC voltage is applied. Thus the output video signal consists of the leading edge of the signal at full amplitude and the remaining part of the signal at reduced amplitude. At the trailing edge of a pulse, the negative voltage on C3 and the AGC

13732

line will discharge quickly through the low forward resistance of diode CR1. In this way, the recovery time following a pulse is reduced to a minimum.

Sensitivity Time Control (STC)

STC provides reduced receiver sensitivity within a range which is variable from 0 to 45 miles from the radar set. This feature may be used to reduce clutter on the indicator CRT caused by close-in targets, such as land masses and sea return.

For STC operation (fig. 18-17) a positive trigger pulse (STC OUT), from the electrical synchronizer, is fed to the grid of V1A in the radar set control. V1A is pulsed into conduction by the input pulse. While V1A is conducting

AT.352

Figure 18-15.–Linear vs. COAC operation.

capacitor C2 is charged negatively. The amount of negative voltage change on C2 is controlled by the setting of depth control (R8). The voltage magnitude controls the amount of reduction in receiver sensitivity. Following the trigger pulse, V1A is cut off and capacitor C2 discharges. The discharge time of C2 is determined by the range control setting. The exponential voltage rise from C2 is coupled through cathode follower V1B. The voltage output from the cathode follower is clamped by capacitor C4 and diode CR1 to the d-c potential provided by the manual gain control.

The exponential voltage amplitude determines the amount of reduction of receiver sensitivity and is controlled by R8, the depth control.

The length of time that the exponential voltage is present determines the range of STC and is controlled by R7, the range control.

AT.353

Figure 18-16.–AGC circuit.

13734

INDICATOR

The indicator accepts the radar data such as video pulses, range marker voltages, and sawtooth timing waves, and represents them in a visual display on the screen of a cathode-ray tube. The entire assembly contains the cathode-ray tube and various electronic circuits necessary for presenting the desired information on the screen. These circuits include video amplifiers, diode clamping tubes, and the controls for adjusting the brilliance of the visual pattern.

Sawtooth timing waves of voltage or current are applied to the deflection circuits of the CRT to produce the time trace or sweep in the pattern. The synchronizing pulse which triggers the modulator and transmitter also serves to coordinate the start of the sweep with the action of the transmitter to make range measurements

AT.354

13735

UNIT VI - DIMENSIONING

The Selection of Dimensions — Lesson 3

OBJECTIVE: To learn how to dimension properly.

RELATED INFORMATION:

The most common shapes the draftsman will encounter in his work are the square, the rectangle, and the triangle. Each of these shapes has three dimensions making up the object - its height, width, and depth - which we must indicate in the dimensioning of the part.

The cylinder is the next most common shape, and here we require only two dimensions, diameter and length. Partial rounds such as fillets are dimensioned by radius instead of diameters. A good rule to remember is this: Dimension full circles with a diameter and partial circles with a radius.

There is no set basic rule for choosing which dimensions to indicate, but the draftsman should try to select dimensions convenient for the workman to use. Therefore the superior draftsman will not be satisfied to know engineering drawing as a language, but he will try to supplement his total knowledge by learning shop methods. In this way, he can dimension from a practical viewpoint and not complicate his drawing with too many dimensions or leave the workman at sea because he has not put in enough.

Always remember in drawing extension and dimension lines that they are drawn lighter than the object lines. The extension lines extend approximately $\frac{1}{16}$ inch away from the drawing.

Oftentimes when holes and diameters are to be dimensioned, or other information must be given that cannot be shown by dimensioning, a note is included instead. Feel free to use notes, for oftentimes this clarifies situations.

QUESTIONS:

1. What are the most common shapes the draftsman will encounter in his work?

2. What is the next most common shape?

possible. Target bearing in most displays is indicated by synchronizing the position of the sweep line on the screen with the position of the antenna.

In addition to video pulses, range marker pips, and sweep voltages, a square wave pulse is applied to the indicator tube which blanks the beam between sweeps so that retrace lines do not appear on the screen.

Figure 18-18 illustrates, in block diagram form, the circuitry of a typical radar indicator for general-purpose use.

Types of Modulation

Two general types of presentation are used in aircraft radar indicators. They are the deflection-modulated and the intensity-modulated displays. The electron beam can be deflected from its normal linear sweep across the screen of a CRT. When this type of deflection is initiated by the radar echo, it is called deflection modulation. If the radar echo is caused to intensify the electron beam of the CRT without deflecting it, intensity modulation results. In both types of modulation, the range sweep is modified at a distance from its origin that is proportional to the target's slant range.

In the deflection method, the video pulse causes a momentary deflection of the cathode ray electron beam and produces a pip in the trace to indicate a target echo. In the intensity method, the video signal is applied to the element of the CRT which controls the intensity

AT. 355

Figure 18-18.–Radar indicator, block diagram.

13736

of the electron beam, and the resulting target image is a bright spot of light. The A–scope is an example of the deflection method and the PPI is a typical intensity presentation.

Spatial Dimensions

Space is commonly considered to have three dimensions; that is, the position of a point in space can be described by three quantities. In terms of radar, these three quantities are slant range (distance), bearing angle (horizontal direction), and elevation angle (vertical direction). A display of information is one-, two- or three dimensional, according to the number of dimensions presented. Thus the reading of a radar altimeter is one-dimensional, and a chart or PPI is two-dimensional. When slant range, bearing, and elevation are all given on a single screen, a three-dimensional display results.

The display of a particular radar is a compromise in the emphasis to be given to the spatial dimensions. The various types of display are designated by letter–A-scope, B-scope, etc.–designation being applied to the presentation itself and, by extension, to the unit that produces it. Thus, the letters PPI are applied to a piece of radar equipment and also to the type of display shown by a plan position indicator.

The more basic facts concerning A-scopes, B-scopes, PPI, and range-height indicators (RHI) are given in Basic Electronics, NavPers 10087-B. Some of this information is reviewed in the following paragraphs, along with additional details relating the various types of scopes of aircraft utilization.

Typical Indicators

The PPI scope is one of the most common types of display for airborne radar. The CRT used in a PPI scan is intensity modulated with the sweep moving radially from the center outward. Basic Electronics, NavPers 10087-B, explains how a voltage applied to a pair of deflecting coils would cause the electron beam to move to one side of the screen, at right angles to the magnetic field. In the PPI scan the time base is applied in this manner; distance is measured from the beginning of the sweep, the center of the screen. If the deflecting coils are made to revolve slowly around the neck of the tube, in synchronism with revolutions of the directional antenna, a polar map is developed on which the range is plotted radially against the position in azimuth through 360°. The top of the screen can represent dead ahead of the aircraft, or it can be oriented to true north. In some aircraft installations it is possible to synchronize the PPI picture with the fluxgate compass so that the top of the screen represents true north.

Range markers are used with most PPI scopes. The timing system is made to produce equally spaced concentric circles about the scope center which show the distances of objects from the transmitter. Muptiples of 5, 10, or 20 nautical miles are often used.

Most PPI indicators use a pair of deflecting coils which are rotated around the cathode-ray tube to produce the rotating sweep. However, if it is desired, it is possible to accomplish the rotation by electrical means.

Many PPI indicators have provision for what is called sector scan. Revolution of the antenna is stopped, and it is caused to move back and forth through a sector up to about 60°. The antenna scans this area at about two to three times the rate of normal revolution. Thus the search area is covered more frequently and targets are observed more distinctly.

There are two ways to view the picture seen of the PPI scope, depending on whether or not azimuth stabilization is used. With the azimuth stabilization in use, the output of the fluxgate compass is tied into the radar set. The PPI scope then becomes another remote compass indicator and the pattern on the scope is seen as it appears on a chart. The top of the scope represents either true or magnetic north, depending on whether variation has been set in.

It is easier to navigate with azimuth stabilization on. A bright line on the scope, known as the lubber line, always points in the same direction that the aircraft is heading. True or magnetic bearings are read on the azimuth scale, and the pattern on the scope is always oriented with the chart.

With azimuth stabilization off, the top of the scope represents true heading. Bearings taken are relative bearings.

A-SCOPE.–On the A-scope, only range is presented, but accurate bearings may be obtained

13737

with auxiliary aids. Ordinarily, a single line (the time base) appears across the scope. If the gain is stepped up, the time base may appear as grass, so called because it looks like grass. (The grass results from amplification of electronic noise when the gain is increased.) When a target is within range, it appears as a sort of peak (called a pip) sticking up from the line or out of the grass. For bearing, antenna rotation may be stopped at the point where the target pip is of maximum size. Bearing may then be read from a counter or dial linked to the antenna.

B-SCOPE.–The B-scope gives bearing and range in rectangular coordinates. The bearing scale is along the horizontal axis, the range scale along the vertical. This presentation is often used in fighter aircraft; the scope shows a sector of perhaps 130° or 150° ahead, with "dead ahead" represented by the center line of the scope. Since the B-scope presentation puts a pie-shaped sector into a rectangular presentation, it is distorted and does not show a "map" of the section it scans. Still, it is close enough to a map to give you a good quick picture of the situation ahead. Since small deviations in bearing become more conspicuous as the target gets closer, it is a good scope to use when closing in on a target or to avoid obstructions. The B-scope gives very good resolution in range and bearing; that is, targets very close together can be distinguished as separate targets.

RHI SCOPE.–An RHI scope is essentially a normal PPI laid on its side so that the antenna scans vertically instead of horizontally. Range is still shown radially, but the angle that was formerly the bearing angle becomes the elevation angle. The vertical plane in which the RHI scans can be rotated about a vertical axis, as the horizontal plane of a normal PPI can be tilted around a horizontal axis. In an RHI, targets in a vertical plane only are displayed. The RHI screen shows a side view of this plane (fig. 18-19), the horizontal axis showing the range in miles and the vertical axis showing directly the height of the target aircraft in feet, and not the elevation angle. Height instead of elevation angle is obtained by electronically combining the range with the sine of the elevation angle. The height scale must be increased or stretched if significiant information is to be obtained, particularly for distant aircraft. Figure (18-19)

AT.356

Figure 18-19.–RHI scope presentation.

shows a height scale which has been stretched so that 5 nautical miles (30,000 feet) is equivalent to about 20 nautical miles of range.

Variations in Scope Presentation

On some scopes used in aircraft all three coordinates–azimuth, elevation, and range–can be obtained. Since scopes are basically two-dimensional, the azimuth-elevation or range-elevation presentation must be superimposed on the range-azimuth presentation, with a switch to select one or the other; or one presentation may be placed above the other so that, in effect, you have two scopes.

Most radars have both long- and short-range scales, and some have several intermediate scales. The long scale may give ranges out to 100 miles or more; the short scale may be less than a mile. For instance, one type of night search and intercept radar has scales of 1,500 yards and 2, 8, 20, 50, 100, and 150 miles. Most antisubmarine warfare radar and airborne early warning radar have a maximum long-range scale of 200 miles. This scale could be very valuable in making a landfall, establishing position in off shore flight, and in the surveillance of maritime shipping.

In a number of radars, a sweep delay control makes it possible to eliminate the nearby areas from the presentation and show only the

13738

areas farther out. This is done by delaying the sweep on the scope. Ordinarily, the sweep on the scope starts at the same instant that the radar pulse is transmitted. Since the closest targets are normally those directly beneath the aircraft, there is a hole in the middle of the picture. This hole represents the distance between the aircraft and the ground. To eliminate this hole, the start of the sweep is delayed by a selected amount equivalent to the altitude. With this delay, called altitude delay, the hole is closed up and objects underneath the aircraft appear near the center of the PPI picture. Altitude delay also performs another function. As it is a measure of the distance between the aircraft and the ground or sea below, it can be used to indicate absolute altitude.

Provisions are also made for sweep delay in larger increments in order to give a more detailed picture within certain ranges. Some equipments provide altitude delay up to approximately 35,000 feet and sweep delay up to 200 miles in units of 10 miles. With a 20-mile range setting and no altitude delay, but with sweep delay set at 20 miles, the picture in this equipment would show returns from the area between 20 and 40 miles distant.

Ground Stabilization

Search radar produces a PPI display that constantly changes as the aircraft moves across an area. Since the sweep starting point represents the position of the aircraft in the center of an area, it follows that the PPI presentation will change as the aircraft travels. Also, any targets on the scope will move across the scope. If, however, a target is selected and the radar sweep is "ground stabilized," the sweep starting point will change and the targets will remain fixed in place on the scope. The radar continues to view only the selected area in which the target lies. This is accomplished by the use of auxiliary ground position indicating equipment and off-centering circuits within the indicator.

Ground position indicating (GPI) equipment continuously indicates the ground position of a flying aircraft from an initial reference point. One of its functions is to show north-south and east-west distances from the reference point on direct reading dials. Its primary function is to furnish voltages which will ground stabilize a radar sweep. The PPI sweep remains fixed geographically.

POWER SUPPLY

In airborne equipment, the primary a-c and d-c voltages are supplied from the aircraft's power system to the various units in the radar system. Within the various power supplies the voltage is stepped up or down, and if necessary rectified, to fulfill the requirements of the radar.

The power supplies used in radar are of many different types–bridge, half-wave, full-wave, voltage doubler, etc., and some have voltage regulating circuits to maintain critical voltage levels. Various types of power supplies are covered in Basic Electronics, NavPers 10087-B, and should be reviewed before you continue the study of this subject. A brief description of a typical 3-phase, half-wave rectifier is given in the following paragraphs.

The primary power supplied to most aircraft radar installations is 115-volt, 3-phase, 400 Hz. A 3-phase, half-wave rectifier acts like three half-wave rectifiers operated so that each rectifier tube plate becomes positive once every 360 electrical degrees of phase rotation. Because of the 3-phase connection of the rectifiers, the circuit will deliver a comparatively large amount of power. The output ripple voltage is 1,200 Hz, and a minimum amount of filtering is required. Figure 18-20 shows a 3-phase power supply and the wave-forms.

The waveforms show that curve 1 starts to rise from point zero. After 120 degrees, curve 2 starts to rise from zero, and curve 1 is starting to return to zero after passing through a peak. After another 120 degrees, curve 3 starts to rise from zero and, at the same time, curve 1 has almost reached a peak in the negative direction, and curve 2 is returning to zero after passing through a peak. After 360 degrees, curve 1 has returned to point zero, curve 2 has returned to point zero after passing through a positive peak, and curve 3 has almost reached a peak in the negative direction. The output waveform is a series of overlapping positive cycles of voltage that never falls below 50 percent of the voltage maximum. When this condition is compared to other forms of rectification, the reason for less filtering is readily apparent. For example, the output waveform of a full-wave, single-phase

13739

rectifier falls to zero volts once for each 180°(ripple frequency 800 Hz), and the half-wave, single-phase rectifier waveform falls to zero once each 180° and remains at zero for the next 180° (ripple frequency 400 Hz).

Since the frequency of the ripple voltage is higher, it is possible to use comparatively small filter chokes and capacitors in a 3-phase power supply. In high-power radar power supplies, gas diodes are used because of their efficiency. However, recent development of high-efficiency, heavy-duty germanium diode rectifiers has resulted in a trend away from vacuum tubes because of savings in space. In addition, no filament power is required for the germanium diodes, which results in even greater savings in space and weight.

CHAPTER 19

PRINCIPLES OF IFF

FUNCTION OF IFF

The age-old problem of distinguishing friend from enemy in warfare increased greatly when aircraft came into use. As faster ships and aircraft have been developed, the identification problem has increased. Although a radar can detect targets (both sea and air) at long ranges, it displays both friend and enemy as similar spots of light on the CRT. With the destructive power of modern weapons and the speed of modern weapon delivery systems, it is not practical to wait until the target has been identified by visual means to begin preparing for battle. Therefore, some method other than visual recognition must be used to identify the target as early as possible.

The problem of identification led to the development of an electronic system that permits a friendly craft to identify itself automatically when interrogated, before approaching near enough to threaten the security of other naval units. This electronic system is called IFF (identification, friend or foe). For operations involving only friendly aircraft, it is important to know not only their location but also the identity of each.

IFF systems are designated by MARK numbers. The IFF mark number is a Roman numeral (Mark X), to prevent possible confusion with fire control radar systems also designated by mark numbers (Mark 29, etc.).

MAJOR AND AUXILIARY UNITS

The IFF system consists basically of a pair of special transmitter-receivers, working in conjunction with a radar set. Figure 19-1 shows the units required for the basic operation of an IFF system. The system is composed of a RECOGNITION group and an IDENTIFICATION group.

The recognition group consists of an interrogator, a responser, and a coder-synchronizer. In airborne equipment, the interrogator and responser are usually contained in the same housing; this is known as the interrogator-responser (IR) unit (AN/APX-71 or AN/APX-72).

The identification group consists of a transponder and provisions for an auxiliary coder. The auxiliary coder, when installed, enables identification on a selective basis; it is thus called the Selective Identification Feature (SIF). Almost every aircraft and ship of the Armed Forces carries a transponder (such as the AN/APX-6 or AN/APX-64), since this is the unit which provides identity when challenged.

Coder-Synchronizer

The coder-synchronizer is the main unit of an IFF system; it enables the system to have three modes of operation on a time-sharing basis. The coder-synchronizer performs two functions–it generates the selected coded interrogation pulses, and separates the received video pulses into the proper channels.

INTERROGATOR.–The interrogator is a pulse type transmitter, triggered by the coder-synchronizer, which acts as the challenger. When a radar operator observes an unidentified target on the radar, he sets the interrogator in operation and it emits coded challenging (interrogation) pulses.

The challenge is a pair of UHF pulses emitted a few microseconds after the radar pulse. There are three types of challenge signals,

13741

AT.302

Figure 19-1.–IFF system.

13742

198

which are transmitted (when selected) on a time-sharing basis, called mode 1, mode 2, and mode 3. Each mode produces a pair of 1-microsecond pulses. In mode 1, the paired pulses are spaced 3 microseconds apart between the leading edges; in mode 2 the paired pulses are spaced 5 microseconds apart; and mode 3 has a spacing of 8 microseconds. The selection of the desired mode of challenge is done at the display station. The challenge signals are synchronized with the pulse of the associated radar, but with a delay of 0 to 40 microseconds introduced.

TRANSPONDER.–The challenge is received by the transponder, which is a pulse type transmitter-receiver unit. Upon receiving the proper challenge, the transponder automatically transmits an identifying reply. The reply is normally transmitted on a different frequency from the interrogation (challenge). The modes of interrogation for, and the response from, an aircraft's transponder (without SIF) are shown in figure 19-1. All pulses are 1 microsecond in width. All time spacing is in microseconds and is measured from leading edge to leading edge.

In airborne equipment, the pilot controls the replies to all modes except mode 1. His selection of replies to all other modes is governed by the operational procedures in use at the time.

The airborne transponder is able to generate an emergency reply for all modes of interrogation if the pilot has the proper switch enabled. The emergency reply comprises 4 pulses; each pulse is 1 microsecond in width, with 16 microseconds between leading edges.

The airborne transponder has a special mode 2 function, controlled by a three-position switch labeled I/P-OUT-MIC. With the transponder replying to mode 1 interrogations only, and the I/P-OUT-MIC switch placed in the MIC position, the transponder will not reply to mode 2 interrogations unless the pilot's microphone button is pressed for radio communications. If the spring-loaded I/P-OUT-MIC switch is held in the I/P position, the transponder will reply to mode 2 interrogations. The response for this special mode 2 is the same as that for normal mode 2.

RESPONSER.–Replies from the transponder are received by the responser in the recognition unit. The replies are converted into video pulses, which are then fed to the coder-synchronizer for separation into the correct mode channels. The output of each channel is fed to a final recognition section. The CRT may be either that of the associated radar set or a separate scope. When displayed on the radar CRT, the video pulses may be displayed separately, or they may be mixed with the radar presentation if desired. Provisions are also provided for an SIF decoder unit.

The airborne replies are shown in a PPI scope in figure 19-1 (B). They are shown as dashed lines beyond the target echo. The dashed effect is due to the mode interlacing action of the coder in the recognition unit. Blank spaces represent the time during which interrogations on the other two modes are sent out. The IFF presentation can be distinguished from the radar presentation by these dashes. The length of the dashed line varies with the range and the radiation pattern of the antenna used with the recognition (IR) unit.

Capabilities and Limitations

In the IFF system, the use of a receiver and transmitter (transponder) at the target not only serves to furnish a strong reply signal for the recognition set, but also permits replies to be made on a different frequency, eliminating clutter. Therefore, the IFF system does not require as much transmitter power as does the search radar. The additional transponder also allows the use of separate codes for replies, thereby providing for increased information. The distinctive coding used for the three modes of operation increases the traffic handling capabilities, eliminates confusion, and provides positive, rapid identification of unknown targets. In the IR unit, time sharing of the three modes permits a number of operators to use different modes without interference or delays.

Because ultrahigh frequencies are used for transmission and reception, the operation range of the Mark X IFF system is virtually limited to line-of-sight distances.

IFF will often provide recognition responses over a greater line-of-sight distance than that over which the search radar (associated with the interrogator) can respond to its own echo signals. The explanation is simple: Radar energy re-

13743

turned as an echo is only a very small percentage of the energy that was initially transmitted from the radar in an ever-widening beam, while the response from an IFF transponder is a much stronger signal that travels only one way–to the responser. The interrogation radar energy that strikes a distant target may be of sufficient strength to trigger the IFF transponder but not to return a usable echo. (For the purpose of this discussion, a usable signal is one having sufficient strength, when returned to the radar receiver, to be detected, amplified, and displayed as a target.) The IFF response in this case will be usable, while the radar echo will be of insufficient strength to be usable.

THEORY OF IFF

INTERROGATOR-RESPONSER AN/APX-7

The AN/APX-7 is an airborne IR unit which forms an integral part of the Mark X IFF system. It consists of Radar Receiver-Transmitter RT-261/APX-7, Coder-Synchronizer KY-84/APX-7, Radar Set Control C-1040/APX-7, and mountings.

The primary purpose of the AN/APX-7 is to challenge the identity of targets which are detected and displayed by the search radar set with which it is associated, distinguishing between friendly targets and enemy targets. In addition, the AN/APX-7 provides detailed recognition information on friendly targets for additional security and tactical purposes. Both the radar and IFF replies may be shown on the same display without compromising the radar's performance.

Functional Block Diagram

Figure 19-1 (A) is a simplified block diagram of an IFF system using Radar Recognition Set AN/APX-7. (The block diagram for a surface craft would be the same; only the components would be different.)

The search radar aboard the aircraft picks up an unknown target. The radar operator, wishing to identify this target, operates his recognition set, causing challenge signals in the form of coded pairs of RF pulses to be transmitted in synchronism with the associated radar set. If the interrogated target is equipped with an operating IFF transponder (APX-6), it identifies itself by detecting and analyzing the coded interrogation and automatically transmitting the reply signals. These replies are picked up by the recognition set, converted into video signals, and displayed on the search radar indicator. By observing this display, it is possible to determine instantly the identity of the challenged target.

Only the recognition set which transmits the challenge signal can synchronize the coded replies for useful display. Replies which are transmitted in response to challenges from other recognition sets also may appear on the radar indicator screen. However, they will be seen as random, nonsynchronous, momentary flecks of light.

The AN/APX-7 is designed so that IFF replies may be displayed on remote indicator units aboard the aircraft as well as on the search radar indicator screen. In addition, all IFF and radar information received and displayed aboard the aircraft can be made available to certain shipboard and other aircraft radars by means of an associated radar relay transmission system.

Time Sharing and Transmitting

The time-sharing function of an IFF system is accomplished by use of a coder-synchronizer. The trigger pulse (cosine pulse) from an associated radar is applied to a countdown multivibrator (fig. 19-2). The multivibrator provides one output for each input trigger, provided that the cosine's PRF does not exceed 320 pps. If the PRF is greater than 320 pps, the output will be the largest submultiple between 160 and 320 pps; for example, 500 pps in - 250 pps out.

The countdown output is then applied to three circuits–the coder (pulse pair generator), the coded IR circuits, and the triple gate generator. The pulse to the triple gate generator is either applied directly or further counted down by a counter circuit which divides the frequency of the pulse rate by a factor 2, 4, 8, or 16, depending upon the setting of switch S1001. The

reason for the second countdown will be described later.

TRIPLE GATE GENERATOR.–The pulse (through S1001) triggers a delay multivibrator (fig. 19-3) whose duration (delay time) is adjustable from 2,700 to 6,200 microseconds. Since the trailing edge of the delay gate is used

AT.359

Figure 19-3.–Triple gate generator, block diagram.

13745

to trigger the gate circuits, generation of the gate is delayed by the same period.

The purpose of this delay is to make sure that mode switching does not occur exactly when a coded pulse pair is being generated. The delay also allows sufficient time after transmission of a coded pulse pair for all replies to be picked up by the receiver. The amount of delay selected is dependent on the associated search radar range, and properly synchronizes the IFF operating range with the radar.

The gate generator furnishes three gating pulses which are used to enable use of modes 1, 2, and 3 in rotating (or time sharing) sequence. Each delayed pulse stops one gate and starts the next. Mode 1 gate starts when mode 3 ends, mode 2 starts when mode 1 ends, mode 3 starts when mode 2 ends. The duration time of each gate is a function of the type of count selected; a 1, 2, 4, 8, or 16 count may be selected (by S1001) in the counter circuit.

CODER.–The coder generates the coded pulse pairs which are fed to the modulator in the transmitter-receiver (interrogator) unit. In mode 1 the pulse generator will generate a pair of pulses that are 3 microseconds apart. Mode 2 pulses will be 5 microseconds apart and mode 3 pulses will be 8 microseconds apart. (See fig. 19-1.)

The trigger pulses from the first countdown circuit (fig. 19-2) are fed to a delay multivibrator (fig. 19-4) which provides trigger pulses that can be delayed from 6- to 50-microseconds (maintenance adjustment). This stage is used to delay the transmission of each pulse pair so that it occurs after the associated radar transmission, thereby, causing the IFF return signal to be displayed beyond the radar return target on the radar scope. The delay multivibrator would be adjusted for a delay of 40 microseconds if the associated radar had a 30-microsecond delay between the generation of the cosine trigger and the firing of the transmitter. Thus, the IFF return would be displaced 10 microseconds after the radar return target.

The output from the delay multivibrator is a positive square wave whose trailing edge triggers a blocking oscillator (fig. 19-4). The output of the blocking oscillator is a positive pulse of approximately 1 microsecond duration which appears across the cathode load resistor in the delay line (fig. 19-5).

The delay line is a lumped-constant line with taps for 8, 5, 3, and 0 microseconds of delay. The outputs from the 3-, 5-, and 8-microsecond taps are coupled to the control grids of the first-pulse-gated amplifiers (fig. 19-6) for modes 1, 2, and 3, respectively. The 0-microsecond tap is coupled to the control grid of the second-pulse-gated amplifier.

The four gated amplifiers (fig. 19-6) are coincidence amplifiers and are normally cut off by the combined negative voltages applied to the suppressor and control grids. These stages will conduct only when positive voltages are simultaneously applied to both the suppressor and control grids. The suppressor grids of modes 1, 2, and 3 first-pulse-gated amplifiers are connected to gate 1, gate 2, and gate 3 output terminals respectively (fig. 19-3) of the triple gate subassembly.

This mode-enabling gate voltage is automatically selected when the operator chooses the desired interrogation mode. The IFF control box has a rotary mode switch for selection of mode 1, 2, or 3. By selecting a particular mode, the appropriate gate relay is energized thereby allowing the positive gate voltage to be applied to the appropriate first-pulse-gated amplifier suppressor grid in the Coder and IR Coder sections.

Therefore, when a mode-enabling gate voltage is applied to the suppressor grid of one of the first-pulse-gated amplifiers, (figs. 19-4 and 19-6) the amplifier will conduct as the positive pulse from the delay line appears on the control grid. As a result, a negative-going pulse is developed across the plate load resistor, R134 (fig. 19-6). This plate load resistor is common to modes 1, 2, and 3 first-pulse-gated amplifiers and to the second-pulse amplifier.

The negative-going output pulse developed across the common plate load resistor is applied first to a multivibrator, (fig. 19-4) then to a cathode follower operated at cutoff. The cathode follower provides a low-impedance output from the coder section and for the input to the modulator of the transmitter section (fig. 19-8). The cathode follower output is also applied to a pulse-stretching network.

The pulse-stretching network consists of a very long RC network that effectively stretches the pulse width from 1 microsecond to at least 9 microseconds. The stretched pulse is applied to the suppressor grid of the second-pulse-gated

13746

AT.360

Figure 19-4.–Delay multivibrator, block diagram.

amplifier (fig. 19-5 and 19-6). Thus, this amplifier will conduct when the delay-line pulse (in moving along the delay line) reaches the 0 delay tap and is applied to the grid of the second-pulse-gated amplifier. The second-pulse-gated amplifier will develop the second negative going pulse across the common amplifier load resistor R134. This pulse is also applied to the pulse forming multivibrator, cathode follower, and the coder section output. For every first pulse generated, a second pulse is also generated. A third pulse can not be generated even though the second pulse is returned thru the stretching network because there is no positive pulse applied from the delay line. The pulse pair is generated only at the PRF rate of the count down multivibrator (fig. 19-2).

In summary, refer to figures 19-4, 19-5, and 19-6. In mode 3 operation and with a single pulse appearing at (B), the following occurs:

1. The pulse will appear at point (C).
2. Point (C) is connected to the grid of the first-pulse-gated (mode 3) amplifier. This amplifier will conduct because the positive gating voltage (mode 3) has been applied to its suppressor grid.

13747

AT.361

Figure 19-5.–Blocking oscillator and delay line.

3. The output from this amplifier creates the first pulse as well as applying it to the pulse stretching circuit. The stretching output places a positive voltage on the second-pulse-gated amplifier suppressor grid. The second-pulse-gated amplifier is now in a condition to conduct when the delay line pulse reaches point (F) and is applied to its grid.

4. As the pulse passed thru points (D) and (E), the first-pulse-gated amplifiers of modes 1 and 2 could not conduct because there was no positive gating voltage applied to their suppressor grids.

5. After a total of 8 microseconds, from point (C), the pulse arrives at point (F).

6. The pulse at point (F) will cause the second-pulse-gated amplifier to conduct because the stretching circuit is holding a positive voltage on its suppressor grid. The second pulse now appears across the common load resistor 8 microseconds after the first pulse.

7. If the operator had interrogated mode 2, rather than mode 3, as the delay-line pulse reached (D), it would have created a mode 2 first pulse rather than the previously mentioned mode 3 first pulse resulting in a coded pair of pulses that are 5 microseconds apart. In mode 1 operation the coded pair would have been 3 microseconds apart.

CODER IR CIRCUITS.–The coder IR subassembly (fig. 19-7) accepts triggers from the first countdown (fig. 19-2), together with the mode-enabling gate pulse from the triple gate circuit (fig. 19-3), and generates three distinctive "coded IR" pulses, one for each mode of operation.

The coded IR pulses occur 15, 20, and 25 microseconds after the trigger which is used to actuate this circuit for modes 1, 2, and 3, respectively.

The selected IR pulse and corresponding IFF video are fed to video time-sharing circuits in the associated radar synchronizer. There they are mixed with data transmission generated in the synchronizer and fed to the relay link. The ONLY function of the coded IR pulses is to permit selection and display of the correct video

13748

AT.362

Figure 19-6.–Pulse pair generator (coder).

at the remote indicator through a relay data system.

UHF TRANSMISSION.–The UHF transmitting section generates, modulates, and transmits coded RF challenge pulse pairs. Figure 19-8 is a simplified diagram of the transmitting section. This section consists of transmitter multiplier Z202, modulator Z102, frequency converter transmitter Z101, and the required power supplies.

The transmitter multiplier subassembly contains a crystal oscillator (V206) and necessary amplifiers and frequency multipliers (V207 through V210) to provide a signal at the required frequency between 336.3 MHz and 343.3 MHz. The output of the transmitter multiplier subassembly is fed to the frequency converter subassembly.

V211 functions as a tripler with the cathode-grid line tuned in the frequency range of 336.6 MHz to 343.5 MHz, and the grid-plate line to the final output of 1,010 MHz to 1,030 MHz.

The input pulse pairs fed to the modulator are positive trigger pulses delivered by the coder subassembly of the coder-synchronizer. These pulses are applied across the primary of a step-up input transformer T401. The transformer is connected in such a manner that the voltage pulses applied to the grid of driver stage V401 are of positive polarity. V401 is biased below cutoff by the negative voltage on its control grid. The pulses appearing at the output of T401 have an amplitude of approximately 160 volts, which drives V401 into heavy conduction. Since the tube is biased below cutoff, and is driven to saturation by the applied pulse, the output is effectively clipped and is essentially a square waveform. The output of V401 is transformer coupled to V402 by means of interstage transformer T402. V402 employs a circuit similar to V401 and develops its output pulse across the primary of T403, a phase inverting, pulse modulation transformer which has two output taps.

13749

The outputs from T403 furnish high-level pulse modulation of the AN/APX-7 transmitter. There are two outputs from T403–a low-voltage pulse pair, approximately 300 to 400 volts; and a high-voltage pulse pair, approximately 2,400 volts. The low-voltage pulses furnish plate voltage for V208, V209, and V210 in the transmitter multiplier. The high-voltage pulses furnish plate voltage to the high-power drivers and output stage (V211 through V214).

Coils Z401, Z402, Z210, and Z211 serve two important functions. The first is their action as peaking coils, isolating the capacitance of the transmitter tubes from the modulator output, thereby improving the video waveform which is applied to the plates of the transmitter tubes. Second, they delay application of the video pulses to the plate until the RF energy in the grid circuit has a chance to build up to its maximum value.

AT.363

Figure 19-7.–IR coder.

The high-power stages of the transmitter consist of coaxial line type cavities using 2C39A lighthouse tubes. The coaxial line type cavity has a high inherent Q and low radiation, making isolation of circuits relatively easy.

Each 2C39A employs two coaxial line cavities, each electrically equal to approximately one-quarter wavelength at the desired operating frequency. One cavity forms the cathode-grid circuit while the other forms the grid-plate tank circuit. Thus, each stage constitutes a grid-separation amplifier with grounded grid. RF excitation is applied to the cathode-grid input circuit, and output is taken from the grid-plate line. Exact tuning for the particular operating frequency is accomplished by means of an adjustable tuning ring in the grid-plate line. (See fig. 19-9.) This ring acts as a variable capacity which effectively lengthens or shortens the cavity according to the frequency being used.

Figure 19-9 shows the physical construction of the 2C39A circuit used in this equipment; figure 19-10 shows the electrical equivalent of this circuit. As seen in these figures, the input RF power is fed to the circuit via a coaxial line whose center conductor extends into the grid-cathode line. RF power developed in this cavity is then amplified by the tube and appears in the grid-plate line. Note that there is no direct coupling between the grid-cathode and grid-plate lines although a common grid line is used. This is true since, at microwave frequencies, current flows only at the surface of the conductor. Consequently, the cathode-grid current flows only on the INNER SURFACE of the grid line. Plate-grid current flows only on the OUTER SURFACE of this line. There is essentially no coupling (at microwave frequencies) between the inner and outer surfaces of the line.

The RF power developed in the grid-plate line is picked up by a loop connected to the inner conductor of a coaxial line at the output of the cavity. This coaxial line transmits the energy to the next stage, where similar construction is used.

The output of the final amplifier V214 is loop coupled to the antenna by means of antenna coupling post Z207A (fig. 19-8) which is mounted between the grid-plate cavity of V214 and first preselector Z207B. The antenna coupling is used

13750

for transmission of V214 output and for reception of a response.

DECODING CIRCUITS.–The IFF replies are picked up and detected by the receiver in the IR unit. The mixed video signals (all three modes) are fed to the input circuit of the video separator subassembly (in the coder-synchronizer). The video separator performs the function of separating the IFF video pulses into three channels, one for each mode.

The function of the video separator is illustrated by the block diagram in figure 19-11. Amplifying is done by a dual stage amplifier that operates without any phase reversal of input to output. A schematic diagram of the amplifier is shown in figure 19-12. The video pulses from the receiver are applied to the cathode of a grounded-grid amplifier. The signal is taken off the plate and applied to the grid of a cathode follower. The input to the cathode follower is limited by V1502A, so that the output does not exceed 6 volts. The output of the cathode follower is applied to the grids of modes 1, 2 and 3 separators and to another cathode follower. (See fig. 19-11 also.) The separators for modes 1, 2, and 3 are biased considerably below cutoff, and the video pulses alone are not enough to cause conduction. Each separator is controlled by a time-shared, positive-going square wave through a gating diode circuit.

AT.366

Figure 19-10.–Type 2C39A, equivalent circuit.

AT.365

Figure 19-9.–Type 2C39A, tube and cavity, simplified.

Mode 1 separator and gating diode are shown in figure 19-12. Modes 2 and 3 separator circuits (not shown) are similar to mode 1.

When a gate voltage is applied to V1503, a cathode follower, the tube can conduct. During the time of the gate voltage, any video pulses coupled to the grid of V1503 from the cathode of V1501 will appear across the cathode load resistor (R1513) of V1503. (Load resistors are front panel mounted potentiometers.)

For the period of time during which a gate voltage is applied to V1503, it is also applied to the mode 1 channel of the interrogator. For this period of time the interrogator will issue only mode 1 challenges; in this manner, only mode 1 replies will appear at the output of V1503.

AT.367

Figure 19-11.–Video separator, block diagram.

TRANSPONDER AN/APX-6

There are several different Mark X aircraft transponders in use, according to the type of aircraft in which they are installed. They all perform the same function and are basically the same electrically. The only differences are different layout of construction (to fit a given space); single unit; or combination with other systems (sharing a common power supply and housing) for the conservation of weight and space.

13753

Functional Operation

The function of an IFF transponder may be more easily understood by referring to the simplified block diagram (fig. 19-13) in connection with the following description. The main signal channel, which is indicated by heavy lines, is arranged in the form of a loop, using a common omnidirectional antenna for reception and transmission. The equipment contains a superheterodyne receiver with broad bandwidth characteristics. The output of the receiver actuates a pulse type transmitter through a decoder and a reply pulse generating circuit.

Interrogation pulses received by the antenna pass through the preselector to the crystal mixer, where they are mixed with the output of the local oscillator. The output of the crystal mixer is filtered to remove the RF components and is fed to the IF amplifiers.

Six stages of amplification are used, in which degenerative feedback and other broadband methods provide wide bandwidth characteristics. Automatic-overload-control (AOC) and automatic-volume-control (AVC) voltages act on some of the IF amplifiers to progressively reduce the gain under conditions of excessive rate of interrogation or high levels of signal. The AOC is intended to prevent overloading of the equipment and also to maintain effectiveness of transponder operation in areas of heavy interrogation, where it is more important that the

13754

Placement of Dimensions Lesson 4

OBJECTIVE: To learn the proper placement of dimensions.

RELATED INFORMATION:

There are no hard- and - fast rules for dimensioning procedures. If possible, however, adhere as closely as you can to the following principles in the placement of dimensions.

1. Dimensions outside the view are preferred.

2. When there are dimensions between views, the extension lines should be drawn from one view, not both.

3. Dimensions should be placed on the view that shows a distance in its true length.

4. Dimension lines in general, should be spaced $\frac{1}{2}$ inch away from the outlines of the view.

5. Parallel dimension lines should be spaced uniformly, with at least $\frac{3}{8}$ inch between lines.

6. Staggered dimensions may be used, depending upon convenience and readability.

7. Always place the longer dimension outside the shorter ones to avoid crossing dimension lines with the extension lines of other dimensions.

8. Dimensions should never be crowded.

9. All notes must read horizontally.

1373 8481

transponder reply to nearby than to distant interrogation. The AVC is intended to reduce the harmful effects of CW jamming. To minimize the effects of strong echo pulses which, in conjunction with other signals, might falsely trigger the transponder, suppression circuits are included in the IF strip.

A diode detector demodulates the IF pulses, and the resulting video pulses are amplified first by two video stages in the IF strip, and then by three video stages, one of which is also a spike discriminator. The AOC/AVC voltages also bias the diode detector to produce the same effects as in the IF amplifiers.

A differentiating circuit, part of the first video stage, decreases the width of single pulses that might falsely trigger the decoders, and also minimizes the effect of strong off-tune interference.

Three decoder circuits block the main channel to all signals except the pulse pair signals with the proper characteristics. Setting the master switch of the radar set control to EMERGENCY automatically insures that all three decoders are operated by their correponding interrogations.

AT.369

Figure 19-13.–Radar receiver-transmitter.

The main signal channel is automatically blocked at the decoders for a short, fixed interval (75 to 125 microseconds) following the transmission of each reply pulse or pulse code group. This prevents the transponder from replying more than once to multiple path interrogations, and helps to avoid overloading. External suppression pulses from associated equipment may be injected into the transponder, through the SUP receptacle, to disable all reply transmissions for fixed intervals, during which the associated equipment can operate without interference.

Whenever one of the decoders is triggered into operation, its output is fed into the reply pulse generator, either directly or through the multiple generator, producing a reply pulse or pulse group. The type of reply is governed by the mode of operation for which the transponder is set and the type of interrogation received. In emergency operation, the reply to every type of interrogation is a group of four pulses spaced 16 microseconds apart. The reply pulse generator circuit determines the proper pulse widths. Provisions are made for external triggering of the reply pulse generator through the BM TRIG receptacle. The purpose of this receptacle is to provide a means of triggering the radar receiver-transmitter equipment either as a testing procedure or as a function of an auxiliary equipment.

The reply pulses are amplified in the driver, the output of which drives a modulator employing a dual tetrode, parallel-connected tube. The output voltage of the modulator is stepped up by a modulation transformer. It is then filtered and delivered to the transmitter oscillator in the RF head. A portion of the driver output is fed back to the multiple pulse generator to provide for multiple pulse replies when required, and a portion is used in the development of the AOC voltage.

The transmitter oscillates for the duration of each high-amplitude modulating pulse. The oscillator frequency is determined by the setting of the L.O. FREQ. tuning control on the RF head of the radar unit. A TR tube in the preselector protects the receiver input circuits while the RF energy is generated by the transmitter oscillator and delivered to the antenna.

13755

RF Head

The RF head receives and transmits pulsed ultrahigh-frequency signals. It employs an integral, enclosed RF section, using a lighthouse tube as a transmitter oscillator, another lighthouse tube as a receiver local oscillator, and a crystal diode as a mixer. The tuned circuits consist of singly and doubly reentrant resonant line chambers. The RF head block diagram (fig. 19-14) indicates the main signal path through the RF head.

Front and top views of the RF head mechanical assembly are shown in figure 19-15. The mechanical assembly consists of three vertical cylinders emerging from a rounded, boxlike lower section. The RF head houses a doubly reentrant resonant line and two singly reentrant resonant lines, used respectively by the transmitter oscillator, the preselector, and the local oscillator.

Coupling to and from the RF head is provided by the following:

1. The horizontal cylinder terminating in the antenna receptacle J401.

2. The right-angle cylinder, which houses the crystal mixer and filters and terminates in the mixer output connector J404.

3. A receptacle (J401) in the transmitter oscillator anode chamber, into which modulation pulses are injected through a cable terminated by connector P411.

4. A feed-through type capacitor (C403) located on the local oscillator chamber, through which the local oscillator plate voltage supply is fed.

5. A 9-pin connector (J454) to which plate and filament voltages are fed.

Special Circuits

TUNING MECHANISM.–The tuning mechanism controls the resonant frequency of the reentrant lines. Three knurled, disk type controls identified as TRANS-FREQ., L.O. FREQ., and RCVR-FREQ. are mechanically linked to pistons which control the frequency of the transmitter, local oscillator, and receiver RF section, respectively. These controls are shown in figure 19-15.

When any one of the controls is turned, its associated piston is raised or lowered in the resonant line. This causes the resonant frequency of the line to change; the direction of change depends on the direction in which the control is rotated. If dial rotation is in such a direction as to cause maximum piston insertion, the lowest frequency is obtained. Maximum rotation of the dial in the opposite direction then causes the piston to be withdrawn from the line and increases the frequency.

For convenience in making frequency settings, each of the tuning controls has a micrometer scale which ranges numerically from 0 to 3 in steps of 0.01. A calibration chart, furnished with the equipment, lists the proper micrometer settings of the three dials for a particular assigned frequency. The receiver is tunable over

AT.370

Figure 19-14.–RF head, block diagram.

13756

a range of 990 to 1,050 megahertz; the transmitter tuning range is 1,070 to 1,130 megahertz.

As shown in figure 19-16, each tuning control has a stationary scale and a movable scale. The stationary scale is graduated from 0 to 3 with scale divisions at 0.25 intervals. The movable scale is graduated from 0 to 25 and makes possible accurate interpolation of the readings of the stationary scale, since a complete revolution of the movable scale equals 0.25, or one division, on the stationary scale.

The movable scale is attached to the knurled dial; therefore, it is rotated by the movement of the knurled dial of the tuning control. Thus to set a tuning control to a particular frequency, determine the correct numerical setting from the

AT.371

Figure 19-15.–RF head. (A) Front view; (B) top view.

calibration chart and rotate the dial until the sum of the two scale readings equals that number.

PRESELECTOR.–As shown in figure 19-14, the preselector is located between the transmitter oscillator and the local oscillator, sharing with the former a common coupling to antenna receptacle J401, and sharing with the latter a common coupling to the mixer. Received signals enter the preselector through J401, and then are transferred to the mixer (together with the CW output of the local oscillator).

Functionally, the preselector is an open circuit, single reentrant, half-wave resonant line, capacitively loaded by a type 1B40 gas switching tube V402. This tube is inserted in the top of the chamber, and its envelope is held between two narrowly spaced contact rings that form the TR gap. During transmission, some of the RF energy generated in the transmitter-oscillator chamber enters the preselector, causing the gas to ionize. This prevents transmitter energy from entering the main signal channel of the receiver. During reception, the TR tube is substantially deionized (although a keep-alive voltage is applied across its electrodes to maintain the gas in a state of partial ionization). Since the energy level of received signals is too low to ionize the tube, the preselector acts as a tuned circuit for the crystal mixer, thus providing a maximum transfer of RF energy from the antenna line to the mixer.

LOCAL OSCILLATOR.–As shown in figure 19-15, the local oscillator chamber is located at one end of the RF head. Energy from its single reentrant line is delivered to the mixer through an iris and the mixer coupling Z406. The oscillator is a type 2C46 lighthouse tube, the output of which is set 59.5 megahertz above the frequency of received signals. The local oscillator circuit is unconventional because it makes use of a factor that normally would disable a single tuned oscillator–a considerable transit time between plate and grid. In a conventional low-frequency oscillator, where transit time is negligible, the grid and plate of the oscillator tube are connected to opposite ends of the tank circuit, as shown in figure 19-17. The phase of the plate-to-grid feedback voltage is shifted 180° to aid the grid input voltage and to produce oscillations in the tank circuit. However, in the present circuit, transit time causes a phase shift of

AT.372

Figure 19-16.–Tuning control.

AT.373

Figure 19-17.–Local oscillator, equivalent circuit.

13758

180° between current leaving the cathode and current entering the plate; and this, for instantaneous values, causes grid and plate voltages to be in phase. This condition would prevent oscillation in a conventional oscillator circuit but, when modified as in the present circuit, produces satisfactory oscillation. This is done by reversing the grid and cathode connections to the tank circuit. The plate and cathode are connected to opposite ends of the tank circuit, and the grid voltage is tapped off at the point on the line that provides feedback voltage of suitable amplitude and phase angle to sustain oscillations.

The local oscillator circuit (fig.19-17) may be considered as a UHF variant of the Colpitts circuit. Capacitance C402 and inductance L402 form a voltage divider that establishes the proper grid potential. Separate RF and d-c cathode ground connections are utilized to isolate any self-inductance in the d-c cathode circuit. Supply choke L403 consists of a portion of the B-plus lead, which is long enough to produce a pronounced inductive reactance at the frequencies involved.

HARMONIC FILTER.–A harmonic low-pass filter (Z407, fig. 19-14) is inserted into the main signal channel between the mixer coupling (Z406), and the crystal mixer (CR401) in order to bypass undesired signals from other equipments operating nearby in the frequency ranges which might interfere with proper transponder operation. The filter consists of a concentric line, short-circuited at the input end, which is less than one-quarter wavelength for the third harmonic frequency (3,090 MHz). The line is supported at the output ends by a ceramic ring. The entire filter is enclosed by a grounded metal shell, which forms a double capacitor with the inner and outer conductors of the concentric line.

CRYSTAL MIXER.–After passing through harmonic filter Z407, the combined outputs of the preselector and the local oscillator are applied to the cathode contact of the silicon crystal diode, CR401. The crystal is mounted so that it minimizes shunt capacitance, while providing an easy means of removal and replacement.

The output of the crystal mixer includes the original carrier frequency, the local oscillator frequency, and combination frequencies of which the difference frequency (59.5 MHz) is the desired intermediate frequency. The IF input circuit is resonant at 59.5 megahertz; therefore, the difference frequency of 59.5 megahertz is fed with a minimum attenuation to the IF amplifiers. Capacitor C406 functions as an RF filter capacitor to bypass the undesired higher frequencies to ground. This capacitor offers 10 ohms (approximately) of capacitive reactance to 1,000-megahertz signals, and still less to higher frequency signals. The crystal current can be measured at the XTAL CUR receptacle; crystal-current measurement serves as a convenient check on the operation of the local oscillator and the crystal mixer.

SIF AUXILIARY CODER AND DECODER

The Selective Identification Feature (SIF) for IFF Mark X was developed for the purpose of expanding the utility of the MARK X system by increasing its flexibility through a multiple-code transponder reply technique.

By such means, selective and individual identification of aircraft is entirely practicable, facilitating ground control of friendly aircraft, providing operational flexibility associated with the identification process, and thereby incurring a measure of additional security in use of the Mark X system.

The Mark X aircraft transponders have the capability of operation with an auxiliary coder group. This coder is not to be confused with the BLACK MARIA. Coder Group AN/APA-89 is the principal airborne component required to equip IFF Mark X with the selective identification feature. Video Coder KY-81/APA-89 comprises the electronically operated portion of the AN/APA-89.

When Coder Group AN/APA-89 is employed with the transponder, normal transponder operation is modified considerably by S103 (fig. 19-13), the NORM-MOD switch. When Video Coder KY-81/APA-89 is being used with the transponder, S103 is placed in the MOD position. In the MOD position none of the multiple-reply or single-reply pulse circuits between the decoders and driver V110 are used. Instead, the reply pulses, in the form of pulse trains, are generated in Video Coder KY-81/APA-89 and injected at the grids of driver V110. Since the transmitter circuitry has not been altered, transmission of

13759

the coded pulse trains occurs in the same manner as if normal replies were being transmitted.

For normal operation without the use of an auxiliary coder, S103 is placed in the NORM position.

THEORY OF OPERATION OF CODER

The output of the receiver portion of an aircraft transponder when used with the AN/APA-89 consists of single, positive pulses of an amplitude of approximately 7 volts and a duration of 1 microsecond in any one of the three modes. The mode of the interrogating signal received by the associated transponder determines whether the input pulse appears in mode 1, mode 2, or mode 3, since the output from the transponder is used to trigger one of the gate generators (See fig. 19-18 for remainder of coder discussion.)

Each of the gate generators is a one-shot multivibrator. In each, the output is a positive gate pulse whose width (between 35 and 55 microseconds) is determined by circuit parameters. The output of the gate generator (only one is operative at any one time) is applied to the common delay-line driver, and to a corresponding crystal-coincidence circuit.

The delay-line driver operates as a blocking oscillator, generating a pulse approximately 1.35 microseconds wide for each gate pulse it receives.

The 1.35-microsecond pulse is applied to the delay line to establish the pulse train. It is also applied to the pulsed sine-wave oscillator for synchronization.

The delay line is tapped at fixed intervals. The pulse output from each tap may be selected by individual switches, through equalizing resistors and crystal-diode isolating elements, for feeding to a common collector bus.

Three distinct common collector buses are used in the equipment, one for each mode. Separate sets of mechanical or electronic switches are provided so that only those pulses which are desired for a pulse train appear on the collector buses. Therefore, the outputs on each mode collector bus consist of trains of pulses, spaced at fixed intervals, as selected by the mode-selector (mechanical or video) switches.

In order to select and transmit the proper mode coding, three crystal-coincidence circuits are used, one for each mode. Each of these circuits has two input terminals. Each circuit will conduct only when the proper input signals are applied simultaneously to the input terminals. The proper coded pulse train selected for the mode is always fed to one input terminal. Fed to the other input terminal is the signal provided by the gate generator for the mode. Obviously, if either of these two signals is absent, no output will be derived from the circuit. Conversely, if both signals are applied simultaneously, an output will appear, but only for the length of time during which the circuit is gated to the on condition by the gate-generator pulse.

The output of the crystal-coincidence circuit consists of a train of pulses substantially equal in amplitude and spacing to that appearing on the mode-collector bus of the mode-collector switches. Further, since the design of the transponder prevents triggering of more than one gate generator at a time, no gate pulses appear at the input of the remaining two crystal-coincidence circuits. For this latter reason, the remaining two crystal-coincidence circuits are not gated to the on condition, and the output signal appearing on the common coincidence bus consists only of the coded pulse train of the mode in use.

Accurate spacing of the pulses in the train is of prime importance. This accuracy is achieved by utilizing the signal from a pulsed sine-wave oscillator to control the spacing. This oscillator, generating a signal whose frequency corresponds to the pulse-to-pulse spacing of delay-line taps, is started by the same pulse which drives the delay line. The oscillator signal is coupled to the second control grid of the coincidence mixer.

The function of the coincidence mixer is to provide an electrical location where the pulses from the delay line, constituting the coded pulse train, may be mixed by being superimposed upon the positive peaks of the signal from the pulsed sine-wave oscillator. Electrically, the pulses derived from the delay line and applied to the first control grid of the coincidence mixer act as gates which allow the tube to conduct. As a result of this conduction, the output of the coincidence mixer consists of pulse-train signals substantially the same as those from the crystal-coincidence circuits but with one significiant exception. Whereas the pulses appearing at the output of the crystal-coincidence circuits have

13760

AT.374

Figure 19-18.–SIF, block diagram.

13761

13760

spacings determined by the accuracy of the delay-line configuration, those pulses appearing at the output of the coincidence mixer have time-controlled spacings determined by the frequency of the pulsed sine-wave oscillator.

The pulse train from the coincidence mixer is applied to the output blocking oscillator. In the process, a ringing circuit is used to shape the individual pulses. The output blocking oscillator generates a train of pulses at a high amplitude across an impedance of 90 ohms for application to the transmitter portion of the transponder.

Pilot Identification (I/P)

Pilot Identification or I/P is accomplished by utilizing a retrigger gate generator operated by the output of the mode 1 gate generator and the "Emergency-I/P Feedback" pulse from the delay line to produce an extra pulse train. Until the I/P feature is desired, the retrigger gate generator is quiescent. When the I/P switch is closed, however, the following takes place: (1) the grid of the first half of the retrigger gate generator is raised to ground potential from its normal below-cutoff level, and (2) the leading edge of the differentiated mode 1 gate-generator pulse applied to this grid initiates multivibrator action. A rectangular pulse is thus produced which corresponds in width to that from the mode 1 gate generator.

The positive pulse generated by the retrigger gate generator is coupled to the anode terminal of a crystal diode inserted in the "Emergency-I/P Feedback" bus. If no pulse from the delay line exists on this bus, the retrigger gate-generator output is effectively shorted to ground by the low impedance presented by the delay-line terminating resistor. If, however, a pulse from the delay line appears on the "Emergency-I/P Feedback" bus, the crystal diode is cut off and the retrigger pulse from the delay line is coupled to the input grid of the line driver. When this pulse appears, the line driver retriggers and an extra train on pulses is generated.

This generation of additional pulse trains in groups of two continues for the length of time the I/P switch is held closed and for approximately 30 seconds after it is opened, provided that incoming trigger pulses actuate the mode 1 gate generator. The 30-second continuation of pulse trains is accomplished by a resistor-capacitor network in the bias circuit of the retrigger gate generator. This network is completely discharged by the closing of the I/P switch. When the switch is opened, the resistor-capacitor combination is allowed to charge from the bias supply. When the combination has charged sufficiently (in about 30 seconds), the retrigger gate generator is cut off and the tube reverts to its quiescent condition.

Emergency

The emergency feature makes use of the same circuitry as does the I/P feature. In addition, however, a relay is provided and is actuated by the closing of the emergency switch on the transponder set control. One set of contacts on this relay is used to connect additional capacitance in the grid circuit of the mode 1 gate generator, approximately doubling the width of the pulse produced by this multivibrator. Another set of contacts shorts to ground the grid return of the retrigger gate generator.

When the relay is energized, the following events take place: (1) upon receipt of an incoming mode 1 trigger, the mode 1 gate generator produces a gate pulse approximately 110 microseconds wide, and (2) the retrigger gate generator performs as it did during I/P operation, producing a positive rectangular pulse approximately the same width as that of the mode 1 gate generator. Again the line driver is retriggered as it was in I/P operation. During emergency operation, however, the number of output pulse trains is increased to four for each mode 1 incoming trigger pulse. When the emergency relay is deenergized, the system reverts to normal and the retrigger gate generator is again quiescent.

Pulse Train Coding

The coding of each mode is accomplished by the use of the octal code. (Reference may be made to chapter 15 of this manual.) Up to three bits are used for each number. This means that we may select a number of 0, 1, 2, 3, 4, 5, 6, or 7 by use of a maximum of three octal bits. For a number such as 37 (eight) two groups of bits in octal form are necessary. They would be 011 octal to obtain the 3 and 111 octal to obtain the 7. Now consider the grouping for the 3 as

13762

group "A" and the grouping for the 7 as "B." Therefore, for a four digit number the grouping from LEFT to RIGHT would be A, B, C, and D. It must be understood at this point that there will be no more than three pulses created to represent each coded number group. To create a 77, six pulses are necessary.

The code structure created by the APA-89 is established on a 20.3-microsecond time base as measured between the leading edges of the "start bracket" pulse and the "stop bracket" pulse. (See fig. 19-19.) The information pulse positions are shown in the composite code train and are used for the pulse coding. Twelve pulse positions are necessary to represent four octal coded numbers. The twelve pulse positions are divided into four equal groups and are designated A, B, C, and D.

Group A and group B pulse positions are used for reply codes in mode 1, mode 2 (6-pulse), and mode 3. Therefore, two octal numbers are assigned. Four-place octal numbers can be assigned to mode 2 (12-pulse) codes.

In mode 1 there are 31 code structures (01 to 73). Mode 2 (6-pulse or two numbers) and mode 3 have 64 code structures (00 to 77).

Figure 19-19.—IFF-SIF reply code structure. AT.375

13703

13725

Mode 2 may be assigned four numbers (0000-7777). In this case, it would have to use all 12 pulse positions and there would be 4096 possible code structures.

To code a reply of 35 (octal) requires that a pulse be present at the prescribed position for start pulse, A1, A2, B1, B4, and stop pulse and that no other pulses be present at the other prescribed positions of the code train. A mode 2 (12-pulse) code of 7264 would have pulses of start pulse, A1, A2, A4, B2, C2, C4, D4, and the stop pulse.

THEORY OF OPERATION OF DECODER

The KY-364/APX Video Decoder is a compact, transistorized instrument incorporating all functional controls and decoding circuitry within a single unit. It provides SIF decoding capability in an airborne radar recognition facility of the IFF Mark X (SIF) system. The purpose of the KY-364/APX unit is to accept mode-separated (SIF) IFF video pulses, process them, and supply decoded output pulses for display as the IFF target on an associated PPI scope. (See fig. 19-20.)

Figure 19-1 shows an overall airborne IFF system without the SIF feature. The specific equipment discussed is used as a teaching vehicle. Although there are many adaptations and later equipment, basically the theory of operation is the same.

Upon receiving a signal resulting from interrogation, the video decoder of the APX-7 supplies output signals for use in conjunction with the associated KY-364 decoder. (See fig. 19-20.) The information pulses of each reply code train are provided by the KY-84 coder synchronizer. A bracket coincident gate is also furnished for the KY-364 decoder.

The code train input is applied to a multiple-tapped delay line and is processed by logic circuits to derive a PASSIVE DECODE signal and a BRACKET DECODE signal. A provision is made to bypass the logic circuits and generate the CODE video output. The video pulse outputs of the decoder are applied to the azimuth-range indicator (PPI type) and are displayed as the IFF target. For each reply-code received from a challenged aircraft, two logical operations are available and, depending on the reply code structure, two discrete signals are generated. The CODE video output is always available since it is not processed through the logic circuits. One of the three outputs, PASSIVE DECODER, BRACKET DECODE, or CODE video, is selected for PPI display by a front panel switch (fig. 19-21).

Passive Decode

The passive decode function is a check for equality between the reply code train and the preset code of the video decoder. If the reply code is equivalent to the preset code, a single decode pulse is generated. (See fig. 19-22 (A).) If it is not equivalent, a decode pulse is not generated. An acceptable code for each of the three operating modes is set individually and can be changed readily by means of code select switches on the front panel. (See fig. 19-21.)

Bracket Decode

The bracket decode function is a check for coincidence of the start and stop pulses that frame an SIF reply code train at precisely 20.3 microsecond duration. A single bracket output is generated (fig. 19-22 (B)) if these two pulses are present. The bracket start and stop pulses are required in any SIF reply code train. Consequently, when selected, the bracket decode output displays responses from all SIF-equipped targets regardless of reply-code and preset-code equality.

Delay Code Video

After the DELAY CODE VIDEO bypasses the logic circuits, it is delayed 40.8 microseconds from the time of input. In the DELAY CODE position, both the SIF pulse coded trains and the basic (non-SIF) IFF reply pulses from all challenged targets are displayed. (See fig. 19-22 (C).)

Additional Features

A degarble feature incorporated in the video decoder is controlled by a front panel switch. When activated, the degarble circuits detect the presence of reply code train interference and prevent decode outputs of garbled pulse trains. This feature partially reduces the occurrence of false IFF target displays. Garble interference is

13764

ASSIGNMENT:

Draw the views of the object shown below and dimension fully. Obtain any dimensions needed to draw the part by scaling the drawing.

1376

AT.376

Figure 19-20.–Airborne Radar Recognition System, block diagram.

created under various and random conditions. The replies of two or more challenged targets at approximately the same range and bearing may be garbled. Multipath reception from a single target may result in a garbled reply; and, in areas of high-density traffic (around large airports), nonsynchronous replies will often cause replies to be garbled. The video decoder has the capability to individually decode four interleaved 6-pulse code trains, or two interleaved 12-pulse code trains. The accurate decode tolerances of the video decoder significantly increases reliability for resolving interleaved replies and rejecting garbled replies.

Selective Identification

Utilization of the selective identification feature (fig. 19-21) may be accomplished as follows:

With the OUTPUT switch in the BRACKET or CODE position, all SIF target replies for the set mode of challenge are displayed on the PPI. Then, by setting the MODE 1 CODE, MODE 2 CODE, or MODE 3 CODE switches to the preassigned code and by placing the OUTPUT switch in DECODE position, a specific target, or group of targets, whose reply-code is equivalent to the preset code is displayed. The MODE SELECT switch may be rotated through its three positions to monitor on the PPI scope each mode of operation. This may be accomplished by sector scanning or on successive antenna revolutions.

Indicator Presentations

A typical PPI display is shown in figure 19-22 for each selectable output of the video

13765

13764

AT.377
Figure 19-21.–Video Decoder KY-364/APX.

decoder. These displays show IFF responses. If radar targets are also displayed, the IFF response appears at a greater range than the radar target because of the preset delay in the IFF equipment.

BENCH TEST AND ALINEMENT

For specific procedures for testing and alinement of specific equipment, refer to the appropriate equipment manual.

The purpose of this section is to discuss various pieces of shop test equipment that are used with the IFF Mark X equipment in general.

AN/UPM-4

One of the earliest pieces of shop test equipment was the AN/UPM-4. This equipment was capable of testing the earlier APX-equipment; but with the advent of the SIF, this equipment became obsolete.

AN/UPM-70

The AN/UPM-70 superseded the AN/UPM-4. It provides complete facilities for performing corrective maintenance on operational (and some test) equipment in the IFF Mark X system. This test set consists of two basic units, an oscilloscope and a coder simulator. It could also be used for making some of the more common tests required for maintenance of radar equipments operating in the 925 to 1225 megahertz frequency range.

The following list briefly outlines the tests that can be performed with the Radar Test Set AN/UPM-70:

1. Measurement of RF power.
2. Measurement of RF frequency.
3. Investigation of RF pulse characteristics.
4. Equipment analysis using simulated IFF Mark X codes, both the basic modes and the SIF codes.
5. Measurement of receiver bandwidth, frequency, and sensitivity.
6. Measurement of PRF.
7. Video pulse analysis.
8. Signal tracing.

AN/UPM-98

The AN/UPM-98 is a single unit test set that has an advantage in the ability to make rapid checks.

It performs the following checks on a transponder and SIF codes.

1. Receiver rapid check of sensitivity and tuning.
2. Transmitter rapid check of power output, tuning, frequency, SIF coding, and emergency and I/P function.
3. SIF coding check.
4. Mark X Coding check (non-SIF).

13766

AT.378

Figure 19-22.–Typical PPI displays.

5. Automatic overload circuit check.
6. Recovery and suppression check.
7. Bandwidth and tuning indicator check.

On the interrogator-responses (IR) unit it will check the following:

1. Count down circuits.
2. Triple gate generator.
3. Coder pulse pair spacing and width.
4. Coded IF pulses.
5. Transmitter frequency.
6. Transmitter power and pulse shape.
7. Receiver sensitivity, frequency, and video output.
8. Suppression adjustment.
9. Receiver gate adjustment.

AN/UPM-99

The AN/UPM-99 Radar Test Set is basically an AN/UPM-4A with a new display unit attached. Individual checks and adjustments may be performed without the necessity of performing the entire procedure.

This test set will perform any check that the AN/UPM-98 can perform.

13766
13767

CHAPTER 20

ELECTRONIC COUNTERMEASURES

It is the purpose of this chapter to introduce the general principles involved in the operation of electronic countermeasures devices. In the discussion which follows, examples of countermeasures equipments are described to illustrate these principles. The descriptions of the units included here are not intended to provide detailed information concerning maintenance and operation, but are given solely to present the broad basic facts which are common to many examples of countermeasures equipments, both old and new.

It is a basic rule of warfare that for each weapon used by the enemy a counterweapon must be developed. This rule is clearly expressed in modern war by the development and use of electronic countermeasures (ECM). The counterweapon in this case is used against enemy electronic equipment–against radar, communication transmitters and receivers, navigation aids, and electronically controlled weapons (such as guided missiles and proximity fuses). The objective of ECM is to make the enemy's use of these electronic devices ineffective.

SIGNAL CHARACTERISTICS

To prepare effective countermeasures against communication systems and navigation aids, information is needed concerning the frequencies of the emissions, the types of modulation used, the polarization of the transmitted waves, and the exact locations of the stations. For countermeasures against enemy radar, much more information is required. The principal signal characteristics of importance are the carrier frequency, the pulse repetition frequency, and the pulse width. In addition, other data are very desirable. These include the type of scan employed, the rate of scan, the beam width, and the polarization of the antenna.

CARRIER FREQUENCY

The carrier frequency of the enemy radar is the starting point from which the other signal characteristics are determined. Knowledge of the frequency is necessary for determining the type of the radar and its probable function and for preparing effective jamming operation.

PULSE REPETITION FREQUENCY

The second most distinguishing characteristic of the radar is its pulse repetition frequency (PRF), which is the number of pulses emitted per second. The PRF value is a factor in determining the maximum range of the unit since it governs the time interval between the pulses. Long range air search radars must necessarily use low PRF values, since the pulses need to be spaced at intervals sufficient to allow echo signals to return from the most distant object within the desired range. Higher values of PRF are used in surface-search radars designed for detecting objects at shorter ranges. Extremely high pulse rates are employed in such equipment as fire control radars, which have very short range but extreme accuracy.

PULSE WIDTH

It is desirable to know the pulse width of radar signals since this value is the basis for estimating the minimum range of the unit. Pulse width is the interval of time during which the radar transmitter is energized; as a result, it

13768

determines the minimum range at which target echoes can be received.

TYPE AND RATE OF SCAN

The type of scan, the method by which the radar beam searches the target area, is a good indication of the nature and action of the radar. Types of scan include 360-degree, sector, lobe-switching, conical, and spiral scans. The simplest way of distinguishing the scan type is by listening to the intercepted signals. Signals from search radars usually cause a whine in the headphones, the tone being produced by the constant pulse rate. In a 360-degree scan, the signal strength varies periodically as the beam sweeps over the search aircraft. As long as the signal variations continue, the radar is searching; but if the sound becomes loud and steady, the indication is that the set has probably detected the search aircraft and is concentrating its attention on it. Fire control radars often use lobe switching in which the beam locks first to one side of the target and then to the other side. The shifting of the beam takes place rapidly and brackets the target while the radar compares the echoes from each beam position. Lobe switching is easily detected by visual indications of the signals on panoramic adapters, pulse analyzers, and direction finders. It also causes a characteristic chatter in the headphones as the beam position varies.

The rate of scan, or number of scanning sweeps made per minute, is related to the probable maximum range of the radar. Slow scanning is characteristic of long-range search sets, while short-range radars and fire control systems employ much higher scan rates. The rate is usually measured in terms of the time required for one scan. The signals are observed on the screen of a panoramic adapter or the scope of a direction finder. The operator logs the time interval between successive indications of maximum signal strength.

BEAM WIDTH AND POLARIZATION

The measure of the beam width gives an indication of the azimuth accuracy of the enemy set. The width of the beam, which is expressed by the number of degrees between the half-power points, is generally computed from data provided by automatic recorders which give information concerning the amplitude of the signals.

The polarization of the radar antenna is considered in planning effective methods of jamming. This characteristic can be determined by use of direction finders of the type which makes a visual display of the reception. The direction finder is equipped with two antennas—one polarized horizontally and the other vertically. Either antenna can be used for reception, and the polarization of the incoming signals is learned by comparing the patterns resulting from each.

A rough determination of polarization can be made by alternate shifting from vertical to horizontal receiving antennas. The antenna which is of proper polarization for the signal being received will provide an audible response indicating greater signal strength. Circular polarization will give approximately a uniform response on either antenna.

PASSIVE ECM

Passive ECM operations are those which cannot be directly detected by the enemy; examples include reconnaissance and search operations, in which enemy transmitters are detected and located and as many as possible of the signal characteristics are determined. Passive countermeasures also include evasive tactics taken to avoid detection, and methods of controlling the radiations from friendly equipments to prevent the enemy from using our signals for homing, direction finding, or for any other purpose.

SEARCH RECEIVERS

The success or failure of an intercept mission depends largely on the proper functioning of the search receiver, the basic type of passive countermeasures equipment. By means of the receiver, the ECM operator detects the presence of radar and radio emissions, monitors enemy transmissions, learns the types of modulation used, and records indications of relative signal strength.

Search receivers are designed for intercepting signals occurring throughout wide ranges of frequency. Receivers are usually equipped

13769

with several tuning units, each of which can be either manually tuned or automatically swept over a selected frequency sector by motor-driven tuning circuits.

Tape and film recorders are used to make records of the signals received by the associated search receiver as it is tuned rapidly through the spectrum. The recording, which is analyzed after the flight, gives information concerning the frequencies of the signals, the amplitude, and the time of reception.

When searching for enemy radar locations, the ECM receiver operates at a fundamental advantage with respect to the radar. Radar detects objects by reflection, or two-way transmission, in which the reduction of signal strength is proportional to the fourth power of the distance covered by the waves. The receiver, on the other hand, detects the radar by a one-way transmission in which signal reduction is proportional only to the square of the distance. As a result, the presence of the radar can be detected at a distance greater than the maximum range at which the radar can detect the search aircraft.

Receiver Operation

Most search receivers employ superheterodyne circuits that can be tuned rapidly over various bands. The extremely wide frequency coverage required is provided by the use of several tuning units, each of which covers a part of the total tuning range of the receiver. Tuning units usually consist of a tuned antenna circuit, a local oscillator, and a mixer stage. The receiver produces three types of output–video signal voltages for use in a panoramic adapter, video signals which are applied to a pulse analyzer, and an audio output for the headphones. (A panoramic adapter is a cathode-ray indicator that enables the operator to sweep a broad spectrum of frequencies during a short period of time.) When a signal that the operator desires to inspect closely is displayed on the adapter, it is fed to the pulse analyzer for closer study.

In figure 20-1, a block diagram of a typical ECM superheterodyne receiver system is shown. The receiver covers a wide tuning range by employing several selectable RF tuners.

Signals intercepted by the antenna are fed to a connection on the receiver through a switching assembly. This assembly enables the operator to select the proper antenna for the frequency range to be covered. From the antenna connection, the incoming signals are applied to one of the tuning units.

The tuning unit (fig. 20-2) contains an RF amplifier, a local oscillator, a crystal mixer, an IF amplifier, and a d-c motor which is mechanically coupled to a synchro generator. The motor is also coupled to a counter which indicates the frequency to which the preselector is tuned. The synchro generator transfers frequency information to a cathode-ray indicator unit.

Since there are no manual controls in these tuning units, they are usually remotely mounted to provide better utilization of space in the aircraft. The d-c motor also automatically tunes the RF amplifier and the local oscillator through their frequency range. When the frequency is too high for use with conventional RF amplifier circuits, tunable cavities are incorporated instead. The popular name for these cavities is "RF preselector."

Mixing of the input signal with the signal from the local oscillator, in a crystal mixer, produces an IF frequency. This IF signal is amplified through several stages of preamplification. The preamplifiers are stagger tuned; that is, each stage of preamplification is tuned to a slightly different frequency. This staggered tuning gives a very broad bandpass which is desirable for video work. Impedance matching is used in the output to feed the signal into the next section, a mixer amplifier.

The mixer amplifier (fig. 20-3) contains a main IF amplifier strip, a second IF amplifier strip, and the video and audio circuits of the receiver. It also contains a sweep oscillator, a fixed oscillator, and beat frequency oscillator (BFO). The BFO is a heterodyning oscillator used for detecting CW or MCW transmissions. The sweep oscillator sweeps through a spread of frequencies equal to the receiver bandpass. The sweep oscillator output is mixed with the signal from the main IF amplifier in the mixer stage to produce a new and lower IF frequency. This system of going from one IF to a lower IF is called double conversion and is done to produce a still lower frequency which is easier to amplify. The lower frequency allows the use of simpler circuitry throughout the remainder of

13770

AT.379

Figure 20-1.–Typical multiple tuner block diagram.

13770
13771

Figure 20-2.–RF tuner block diagram.

the receiver. This second IF signal is fed through several stages of amplification, then to a detector stage. The detector stage produces a video pulse which is available for presentation on the panoramic and pulse analyzer scopes.

During broadband operation the receiver may receive one or more signals simultaneously. In order to view one signal at a time, the receiver is switched to narrowband operation. Since it is mechanically difficult to stop the sweeping oscillator at the exact frequency needed for double IF conversion, a fixed oscillator is provided. The signal from the fixed oscillator is fed into the mixer during narrowband operation.

From the main IF amplifier strip a signal can be detected, amplified, and then made available as a video input for some auxiliary equipment such as a pulse analyzer, a direction finder, or a remote indicator. Provisions are also incorporated so that any signal present will be amplified through an audio circuit to give an audio tone. This tone may be used to aid the operator in detecting signals. He can listen as well as look. This is desirable since eye fatigue is a problem when he must look at the scope continuously.

From the second IF of the mixer amplifier the video signal is fed to the CRT indicator for panoramic or pulse analyzer indication. The signal may also be fed to auxiliary equipment for further pulse analyzing or direction finding.

WAVE TRAPS.–Search receivers of the superheterodyne type often produce spurious responses caused by image reception in which a station is received at two different positions of the tuning dial. A second type of spurious response also frequently occurs; it is caused by harmonics of the local oscillator. These harmonics beat with strong signals being received at frequencies other than that indicated by the dial, and produce the intermediate frequency with the result that the unwanted stations are heard in the output.

There is another type of spurious response, called pseudoimage frequency, which is a strong signal beating with the fundamental

13772

AT.381

Figure 20-3.–Mixer amplifier block diagram.

IF frequency. Since one of the primary functions of the receiver is to enable the operator to determine the frequency of an intercepted signal by means of the dial reading, some device is needed to assist him in distinguishing true signals from spurious responses. For this purpose, wave-trap stubs or tunable filters are often used in conjunction with these receivers. The wave-trap stubs have a dial calibrated in frequency and can be switched into or out of the antenna lead-in. When the trap is in the circuit and tuned to the frequency of an incoming signal, the signal is filtered out and disappears from the output. By means of the calibration on the wave-trap, the operator can decide whether or not the signal frequency is actually that indicated by the dial reading at which he receives it. Generally, ECM receivers used in the fleet today have image rejection ratios sufficient to permit direct dial readings.

Automatic Search Receivers

Modern ECM receivers use automatic tuning. The receiver's tuning section is driven by an electric motor which tunes the receiver across its entire tuning range. The tuning is continuous; that is, when the upper end of the tuning range is reached, the motor automatically reverses and the receiver is tuned down to the lower end of the band where again the motor reverses and the receiver is tuned to the upper end of its range.

"Fully automatic" search receivers are similar in operation to those called automatic. However, there is one major difference. This difference is that fully automatic search receivers automatically stop tuning operations when a signal is detected. (NOTE: This is usually referred to as receiver lock-on.) The signal may then be observed and its frequency noted by the operator. When the operator completes his observation, a button is pushed (on

13773

the control box) and the tuning drive again starts through its tuning sequence from the point at which it was last locked.

Panoramic Adapters

Panoramic adapters are specialized indicators. Used for monitoring a wide range of frequencies, they provide visual displays of the signals intercepted by the search receiver. The signal indications appear on the screen of a cathode-ray tube. The station to which the search receiver is tuned appears as an inverted-V deflection at the center of the screen; and signals above and below this frequency show similar deflections to the right or left of center, depending on their values. The amplitude of any deflection is determined by the strength of the corresponding signal, so that the panoramic screen provides a plot of signal intensity versus frequency. (Signal intensity is indicated on the vertical axis, and relative frequency is represented on the horizontal.)

In search operations, the panoramic adapter is used principally as a tuning aid since the signals from many stations are indicated simultaneously. It can also be used to determine the types of modulation of intercepted signals and for observing the effects of the search aircraft's own jamming emissions.

INTERPRETATION OF PATTERNS.–Since a comparatively large number of signals may be observed simultaneously on the screen of the panoramic adapter, the instrument has great value in detecting enemy transmissions. Furthermore, the experienced operator can obtain additional information concerning the nature of the transmissions by inspection of the patterns. The oscillograms produced by several types of signals are shown in figure 20-4.

A constant carrier appears as a deflection with fixed height as shown in (A) of figure 20-4. Amplitude-modulated carriers appear as deflections which vary in height. If the modulating frequency is high, the sideband frequencies appear separately, causing pips on either side of the carrier deflection. Modulation with a single audio tone produces the pattern shown in (B) of the figure. A frequency-modulated carrier appears to wobble to the side. When the carrier is frequency modulated by voice or music, the appearance is a number of deflections which spread across a variable band as in (C). Pulse modulation gives the pattern shown in (D) when the pulse repetition frequency is considerably greater than the rate of sweep of the indicator beam.

AT.382

Figure 20-4.–Panoramic adapter patterns.

A CW signal appears and disappears with the keying of the transmitter. Two signals which are near enough in frequency to produce an audible beat note appear on the screen as a single carrier which varies in amplitude at the beat frequency. Noise voltages which vary regularly produce deflections which move across the screen in either direction, the motion being caused by the fact that the noise pulses are not synchronized with the panoramic sweep. Noise and interference, such as static bursts which are not periodic, produce irregular deflections and flashes along the length of the screen.

If image reception takes place in the associated receiver, the image signal has the same sort of appearance as the true signal. However, when the receiver tuning dial is rotated, the image pip moves in the direction opposite to that of the true signal deflection.

PULSE ANALYZERS

Pulse analyzers are used in ECM operations for measurement of the pulse repetition frequencies and pulse widths of radar signals de-

13774

UNIT VII - WORKING DRAWINGS

Scale of Drawings Lesson 1

OBJECTIVE: To learn how to increase or decrease the size of a drawing.

RELATED INFORMATION:

Oftentimes the draftsman is confronted with the problem of drawing a particular piece part on a size of paper either too small or too big for this particular job. He then either increases or decreases the size of the drawing but always maintains the same size dimensions.

As an illustration, the draftsman must draw a flat washer 8 inches in diameter and 1 inch thick, with a 2-inch hole directly through the center. In all probability he would reduce the scale of this drawing to either half or quarter size, but he must still draw the 8-, 1-, and 2-inch dimensions. He does this to reduce the cost of paper and produce a clearer drawing. A note shall also be made that the drawing has been reduced to a particular scale. The decision to either reduce or increase the scale of a drawing rests with the draftsman, and only experience will aid him in his choice of decisions.

QUESTIONS:

1. Why is a drawing size increased or decreased?

2. Whose responsibility is this?

3. If a drawing is increased in scale, which dimensions are put on the field of the drawing?

4. How does one determine what scale a particular drawing has?

5. Always try to maintain full scale on a drawing. Explain.

1375

tected by search receivers. The analyzer can also supply information concerning lobe switching, rotation rates, and beam widths of radar transmissions. In many pulse analyzers, the data are presented visually by means of cathode-ray tubes, although in some the pulse width and PRF values are indicated on meters. An example of the type using a cathode-ray tube as an indicator is shown in block diagram form in figure 20-5. The equipment shown is a synchroscope. (A synchroscope differs from an oscilloscope in that an input signal must be used to trigger the sweep. In actual practice this signal results from the interception of an enemy transmission.)

This analyzer's cathode-ray tube is unique in that it contains five separate electron guns within one glass envelope. The horizontal beam of each electron gun sweeps at a different frequency. Therefore, the signal that appears is shown on five different time bases. Various scales are engraved on the cursor so that desirable readings may be obtained. The two top traces show wide pulses so that pulse width may be observed. The three bottom traces indicate pulses repetition frequency.

The pulse from the search receiver follows two paths after it is fed into the pulse analyzer. One path leads to a pulse shaper which produces pulses having the same width and repetition frequency as the received video signal, as well as constant amplitude and rise time. The shaper output starts the horizontal sweeping action that unblanks each scope.

The other path is through a delay line to the vertical plates of the five guns in the CRT. This delayed signal is the deflecting voltage which produces a deflection of each time base so that signal characteristics are indicated. The delay is for a very short period of time. This insures that the leading edge of the pulse will be presented on the scope. In the last three electron guns, the horizontal sweep frequency is sometimes so low (slow sweep) compared to the signal frequency that the signal does not appear on the CRT. (Signal pulses appear but are too narrow to be seen.) In this case a stretching circuit can be switched in. The stretching circuit broadens, or stretches, the signal enough so that it shows on the scope.

When lobe switching is used by the enemy, the pulse width pattern appears as shown in figure 20-6. Because of lobe switching, the trace is not steady but appears to jump up and down. Although figure 20-6 shows a lobe-switching pattern on only one line, in actual practice the pattern would appear on all five lines.

Cathode-ray oscilloscopes and audio oscillators are sometimes used to measure the repetition frequencies of radar pulses when a pulse analyzer is not available. The pulse repetition frequency is determined from the patterns which result from application of the received signal to the vertical deflection plates of the scope while sweeping the beam horizontally with the output of the calibrated audio oscillator.

The information derived with these various types of search equipment consists of the characteristics of the enemy signals. These properties form the basis for estimating the capabilities and weaknesses of the electronic installations and for devising effective jamming techniques to be used against them.

DIRECTION FINDERS

One of the essential things to learn about any radar or radio station operated by the enemy is its exact location. In search intercept flights this information can be obtained by the use of airborne ECM direction finders which have been developed for this particular purpose. The enemy transmitter reveals its location as long as it is sending out radio waves; but the problem of analyzing the emissions is complicated by the fact that the enemy may choose either vertical or horizontal polarization. Consequently, the direction finder must be capable of receiving either type of transmission.

In ECM direction finders designed for higher frequencies, typical equipments employ continuously rotating antennas which are highly directional. Signals received are displayed on a cathode-ray indicator on which is presented a polar diagram of reception obtained throughout 360 degrees of rotation of the antenna. The pattern contains a major lobe which indicates the relative bearing of the station whose signals are displayed.

To locate a particular transmitter, the operator makes several readings of its relative bearing by means of the direction finder display. Each of these readings is called a "cut." With each cut, the operator records the time and the

13775

AT.383

Figure 20-5.—Block diagram of a pulse analyzer.

13776

AT.384

Figure 20-6.–Pulse width pattern obtained from lobe switching.

compass heading of the aircraft. This information is given to the navigator, who can determine, from the track of the flight, the exact location of the aircraft corresponding to each direction-finding cut. The track of the aircraft is then drawn on a chart and along it is marked the position at which each cut was made. Through each position a line is drawn, which makes an angle with the track equal to the recorded value of the relative bearing for that point. The intersection of the lines on the chart indicates the position of the enemy transmitter.

The direction finder display can also be used to learn the types of modulation of intercepted signals, to estimate pulse widths and repetition rates, and to determine the polarization of radar antennas.

Indicator Patterns

The cathode-ray screen of ECM direction finders employing visual displays shows the operator a polar graph on which the strength of received signals is plotted against relative bearing. To form the patterns, signals are received by the rotating antennas which are synchronized with the sweep of the cathode-ray beam of the indicator tube. Signals are received from a very small sector at any one time and are amplified and detected in the search receiver. Video pulses from the receiver are applied to the direction finder for further amplification. When they are applied to the indicator tube, they produce patterns similar to those shown in figure 20-7.

With each video pulse the electron beam in the CRT is deflected outward from the center of the screen; thus the length of the trace indicates the relative signal strength. The angular direction of each trace line represents the direction in which the antenna is pointing when the corresponding signal is received. The indicated bearing can be either relative or true, depending on the type of direction finder being used.

To read the relative bearing of a station when its signal is displayed, the operator uses a movable mask on which is inscribed an arrow; the mask is fitted over the indicator screen. The operator rotates the mask until the arrow bisects the major lobe of the pattern and then reads the relative bearing on a graduated scale surrounding the face of the indicator tube. In an indicator that reads true bearing, the azimuth scale is automatically rotated around the outer rim of the CRT.

SIGNAL CHARACTERISTICS.–Signal characteristics which create a distinctive pattern on the CRT are radar PRF, relative signal amplitude, modulation characteristics, and polarization. The best way to gain skill in interpreting the great variety of patterns that may possibly appear on the CRT is by observing known scope patterns (characteristics). (Refer to figure 20-7 for illustrations of representative scope patterns.) A certain amount of deduction will inevitably be necessary because of the almost infinite number of possible pattern combinations.

The pattern shown in (A) of figure 20-7 results from the signals of a search radar located dead ahead of the aircraft. The PRF is a comparatively low value as indicated by the wide spacing of the traces. Bright tips appear at the trace ends which are characteristic of pulse-modulated waves such as those emitted by almost all radar transmitters. In (B) of the figure the indicator pattern is that resulting from simultaneous reception of two radars on different bearings.

In (C) of figure 20-7 the pulses are grouped in sets of different length, indicating a lobe-switching radar, possibly a fire control system. The pattern varies with the location of the search aircraft relative to the direction of the radar lobes. When the pulse groups form a smooth pattern with all traces of equal length, the indication is that the aircraft is being bracketed by the switching lobes of the radar and that the guns controlled by it are probably trained on the observer.

13776 13777

AT.385

Figure 20-7.–Direction finder patterns.

13778

A signal from a communications transmitter employing voice modulation is shown in (D) of the figure. Communication signals are easily identified by the fact that they do not produce bright tips on the trace lines and the pattern has a fuzzy appearance. The pattern shown in (E) does not display a marked major lobe and indicates that the polarization of the direction finder antenna is different from that of the polarization of the received waves.

In radar patterns, the lengths of the bright tips on the trace lines provide a means of estimating the pulse width. With the unit whose display patterns are illustrated in (A) and (B) of figure 20-7, the ratio of the bright length to the total trace length expressed in percentage is approximately equal to the pulse width in microseconds. For example, if the bright tip is about 5 percent of the trace length, the pulse width is approximately 5 microseconds. The pulse repetition rate of the radar can be estimated roughly by the amount of spacing between the trace lines; however, the spacing is governed to some extent by the rate of rotation of the receiving antennas as well as by the PRF of the signals.

Equipment Components

An example of ECM direction-finding equipment which provides the type of display discussed above is illustrated in figure 20-8. This direction finder, when used with suitable radio or radar receivers, provides visual indications on a CRT. Such indication gives the true bearing of the received radio or radar signals. The direction indication is converted to true bearing by an azimuth scale which rotates around the outer rim of the CRT. Other information can be obtained from the CRT picture, such as approximate PRF, relative signal amplitude, modulation characteristics, and signal polarization.

AT.386

Figure 20-8.–Block diagram of an ECM direction finder.

The typical direction finder consists of five major units. These are an antenna unit, an antenna drive assembly, an amplifier/power supply unit, an azimuth indicator, and a control box. The type of receiver used was previously discussed. Its output video signal is supplied to the amplifier/power supply unit; this unit consists of a video amplifier and the power supply necessary to operate the direction finder.

The azimuth indicator unit contains a small CRT indicator. It has external adjustments for controlling the vertical and horizontal positioning, and the focus and intensity. The indicator unit also has a torque unit and a gear train These rotate the moving scale for the azimuth reading.

The control box is located at the operator's position. It provides means for selecting the proper antenna, varying the speed at which this antenna is rotating, switching the polarization of the antenna, varying the gain of the video amplifier, and turning the primary power off and on.

The antenna drive assembly has a d-c motor and a gear train to drive the resolver and the antenna. The video signal from the intercept receiver is amplified and then passed through the resolver which is geared to the antenna drive shaft. This resolver voltage is then delivered to the plates of the CRT. It impresses on the tube a signal which is a radius vector rotating about the center of the CRT. The rate of rotation is the same speed as the antenna's rotation.

The combined function of all of the units that make up the direction finder is to produce a CRT pattern of the received radio or radar signal. This pattern is produced in such a manner as to indicate the direction from which the signal is being received and then to convert that direction indication into a true bearing by means of the rotating azimuth scale.

13779

ANTENNAS

The antenna assembly is an essential unit of an ECM installation. Ideally there would be two directional antennas for each frequency range, one polarized vertically and the other polarized horizontally. From the standpoint of space and weight this is impractical for aircraft installations. Aircraft ECM antennas are constructed so that they cover a broad band of frequencies and possess different polarization characteristics. Also, more than one antenna is mounted on the same antenna base. In many of the units, the assembly includes built-in impedance-matching sections.

Direction Finding Antennas

Figure 20-9 shows a type of construction that is used in ECM direction finder antennas. Notice that there are three separate directional antennas. This practice makes possible the coverage of different frequency ranges. Also notice the different types of polarization used.

The three antennas are mounted on the same disk and may rotate through 360 degrees. Only one antenna is active at a time as selected by a polarization switch on a remote control panel. This polarization switch selects the frequency band desired and the type of polarization used with the selected antenna. The feed of the parabolic reflector antenna is rotatable through a 90-degree angle to provide for reception of both vertically and horizontally polarized signals.

Search Antennas

Since enemy signals may appear over very wide ranges of frequency, the antennas used with ECM search receivers must necessarily be very broad in frequency response. To insure this, the antennas are made thick and stubby in structure so that the inductance value is low. As a result, the antenna stores very small amounts of energy and has a low Q with the broad frequency response which is characteristic of all low-Q circuits.

AT.387

Figure 20-9.—Direction finder antennas.

13780

A type of ECM antenna used with airborne search receivers is shown in figure 20-10.

The stub antenna consists of a wooden mast about 22.5 inches in length which is covered with a thick metal plating. The plated area in a typical installation is connected to a receptacle for attachment to a 50-ohm coaxial cable.

ACTIVE ECM EQUIPMENT

Active ECM actions can be detected by the enemy and tend to prevent him from making effective use of his equipment. These actions consist of jamming, of deception, or a combination of both. The equipments used are of two general types: electronic and nonelectronic. The electronic type includes jamming transmitters and pulse-repeating receivers. The jamming transmitters are used to produce interference with radar, navigation, and communications reception so that enemy receiver are subjected to obscuring and confusing radiations. Pulse-repeating devices are used for deception and are similar to radar beacons. They receive radar signals and respond with pulses which give the enemy false information concerning bearing or range.

AT.388

Figure 20-10.–Stub antenna.

Nonelectronic jamming is often accomplished by the use of strips of metallic foil released from aircraft (and sometimes fired in projectiles). The falling strips intercept radar waves and reradiate them, causing numerous false targets to appear on the enemy radar-scope so that the operator is unable to detect desirable targets and fire control radar is unable to see attacking aircraft.

Before active countermeasures can be undertaken, an extensive search, or intercept, campaign must be made to learn what types of electronic equipment are in active enemy use and the purposes for which they are employed. To gain this information, intercept flights are made in aircraft which carry special ECM equipment. With the equipment, the ECM operator tunes in signals from enemy units and measures their characteristics. He records the results in a log or acquires tape or film records which are later submitted to tactical officers for analysis and evaluation. The information gained is then used in planning active countermeasures, such as jamming, for directing control of radiation from friendly units, and for devising means of evading detection by the enemy equipments reported.

JAMMING TRANSMITTER

Electronic jammers are tunable radio transmitters used for producing interference. The jammer radiates a carrier wave modulated with audio voltage suitable for drowning out reception or overloading enemy receivers. One of the most effective kinds of modulation for this purpose is random noise similar to the background disturbances heard in sensitive radio receivers when no station is being received. Noise makes a very desirable jamming signal since it distributes energy over a wide range of frequencies and cannot be filtered without loss of the desired signals. It is also difficult to recognize as manmade interference because of its similarity to atmospheric static impulses. A second type of jamming modulation is caused by sweeping the carrier over a wide range of frequencies at an audio rate. Another type consists of a repetition of several audio tones, three to five in number, which give rise to a wailing sound when received.

13781

13780

When operated against radar receivers, the ECM jammer works at a distinct advantage since the echoes returned from most targets are very weak, and the jamming signal usually competes only with low-level radar signals. An output power in the order of tens of watts can effectively overcome radar pulses originally emitted at a peak power in the order of kilowatts. As a result, low-powered transmitters can sometimes jam enemy radar reception at far greater than the maximum effective range of the radar. However, it is often necessary that the jamming signal be radiated continuously, and that the output power of the ECM transmitter be as great as the average power of the radar it can successfully jam. Because of these requirements, adequate cooling must be provided. This is usually accomplished by fans, but may be accomplished by other means such as a water jacket around the transmitter to remove the heat.

ECM transmitters are used in one or two ways, called spot jamming and barrage jamming. In the first of these, the operator tunes the jammer to the exact frequency of the receiver to be victimized by first tuning in the enemy signal with a search receiver. He then adjusts the output of the transmitter until the two signals coincide in frequency. Tuning for spot jamming is usually done in flight. Barrage jamming is accomplished by using a number of transmitters as in a formation of aircraft with each aircraft carrying at least one jamming transmitter. The units are pretuned to frequencies which differ by about 3 megahertz, a typical value of the bandwidth of an ECM transmitter. When all units are turned on, a wide range of frequencies is completely covered.

An example of an airborne jamming transmitter is shown in block diagram form in figure 20-11.

The typical countermeasures transmitting set is an airborne noise-modulated transmitting system. It is designed to jam enemy radar signals of any polarization over a wide frequency range. Such a transmitting set is suitable for use as a spot or sweep jammer, and for manual use with currently used ECM receivers. This set is a lightweight, airborne, noise-modulated jamming system which may be controlled either automatically or manually. The jamming transmitter is similar to the ECM receiver in that it covers a wide frequency range by using plug-in tuning

AT.389

Figure 20-11.—ECM jamming transmitter.

heads. The noise source is generated by a special type tube. This noise is amplified through several stages of video amplification. This broad band of frequencies is fed to a pair of high-powered modulator tubes.

The RF oscillator stage is the stage that is replaced when different tuning heads are used. Each stage contains a mechanically tunable magnetron oscillator which is modulated by the generated noise signal. The cathode filament of the magnetron receives enough power from back bombardment of electrons, when plate voltage is supplied, to materially shorten the life of the magnetron. Therefore, a-c power applied through the filament transformer must be varied to keep filament temperature constant. This is the function of the filament control unit.

The operator selects the mode of operation of the transmitter with the control box. Transmitter frequency may be changed manually by the operator turning a knob, or it will change automatically if set for automatic operation. A switch is incorporated on the control box which allows the operator to switch out the noise generator. When this is done the transmitter produces CW transmission; otherwise the output is modulated. The purpose of this switching arrangement is to produce another confusion factor for the enemy.

Automatic Jamming Equipment

Automatic jamming equipment consists of an automatic search receiver and an automatically tuned jamming transmitter.

The sequence of operation is as follows: The receiver searches a desired frequency range, and when a signal is detected, the receiver locks-on this signal. As the receiver locks-on, the

13782

transmitter is automatically tuned to the same frequency. When the transmitter tuning cycle is completed, the transmitter is then automatically keyed to begin jamming operation. Different types of jamming (pulse, noise, etc.) may be produced by the transmitter. The particular type of jamming to be used by the transmitter is preselected by the ECM operator.

It should also be noted that this system may be switched to manual operation. This enables the ECM operator to manually perform the sequence of steps in the operation of the system.

ANTIJAMMING CIRCUITS

An ECM development relating to active jamming is the antijamming circuit often installed in receivers, particularly those in radars. The antijamming device is designed to decrease the effectiveness of enemy jamming and hence is called a "counter-countermeasure." These circuits have two uses: They prevent interfering signals from overloading the receiver, and tend to separate the desired signals from the jamming signals. Typical antijamming circuits are simple inductance-resistance filters of the high-pass type. The effect of the circuit, which is usually associated with the video detector section in the receiver, is to pass the high frequencies present in the signal and suppress low-frequency components. As a result, the leading edges of pulses are accepted by the circuits following the filter and large blocks of jamming voltages are excluded from the video amplifier circuits.

NONELECTRONIC JAMMING

WINDOW and ROPE are code names for strips of aluminum foil used for nonelectronic jamming. The strips act as reflectors; and when released from aircraft, they return echoes to enemy radar receivers.

Window

Window (also called chaff) is tuned material. The strips of foil are cut to one-half wavelength of the radar signal to be reflected, and each strip acts as a resonant dipole antenna which intercepts and reradiates energy. The dipoles are packaged in cardboard folders which are either dropped manually or released by automatic window dispensing devices. Each package contains foil cut for a certain frequency so that a folder may contain from 50 to 200,000 dipoles, depending on the wavelength of the system for which it is prepared. Typical bundles contain several thousand strips, and weigh less than two ounces. When the package is released, it opens so that the dipoles scatter into the air and begin falling at the rate of about 400 feet per minute.

Skilled radar operators can distinguish between aircraft pips and a single window echo; for this reason, window is seldom dropped in isolated packages. Usually, a lead aircraft lays down a path consisting of many packages spaced at intervals of 1,000 feet or less. The aircraft which follow in the formation fly through the resulting clouds of reflectors, and enemy operators find it difficult to separate the single pip of an aircraft from the mass window echoes. Thus, the following aircraft are protected from radar-controlled antiaircraft fire and concealed from air search radars. On the radarscope, the dispensing aircraft appears as a pip which divides into two parts. The pulse representing the aircraft moves across the screen while additional echoes appear behind it and remain stationary. As the dipoles disperse in the air, the stationary pip grows into a shapeless mass in which the following aircraft are practically invisible. Aircraft must be inside the cloud of reflectors to be hidden; those behind but not within the cloud can be detected by radar waves which pass through the strips.

Window is often used in conjunction with electronic jamming transmitters to protect a formation of aircraft from radar-controlled gunfire.

Rope

Rope is similar to window in that it is a confusion reflector, but it differs from it in length and also in the fact that it is untuned. Strips of rope are aluminum ribbons about 400 feet in length and about one-half inch in width. The ribbons are used as nonresonant reflectors for jamming low-frequency radars and are also employed in regions where the enemy operates many units which differ considerably in frequency. The rope material is dispensed in the form of a roll, one end of which is attached either to a small paper parachute or to a square

13783

13783

of cardboard. The rolls equipped with parachutes assume a vertical position while falling and reflect waves that are vertically polarized. Those attached to cardboard squares unwind and float downward in a horizontal position, thereby reflecting horizontally polarized radar pulses.

CHAFF DISPENSERS

Chaff dispensers, together with the dispenser control (fig. 20-12) are designed for use with a variety of military aircraft. Their purpose is to carry and dispense packaged chaff material for jamming and deceiving enemy radar equipment. They are similar in size and shape to a droppable fuel tank, and have a large container inside for carrying the chaff material.

The chaff material is held firmly in place in the container by the package holddown assembly. (See fig. 20-13). The holddown assembly is in the DOWN position (after loading) until ready to dispense the chaff material. To start the operation the operator moves the DISP-OFF-HOLD switch from HOLD to the DISP position, energizing the holddown motor and raising the holddown pad until the pad actuates an up-limit switch (normally open) supplying power to the drive motor. The drive motor pulls the tape, which carries the chaff material aft over the idler rollers and into the airstream coming from two air ducts in the dispenser body. The airstream deflects the chaff material down and out of the opening in the aft underside of the dispenser. A tape cutting feature is incorporated in the dispenser to prevent long streamers of chaff tape fouling the packages or tail assembly of the carrying aircraft. An automatic motor disconnect switch is provided to automatically open the motor circuit when all the chaff packages have been dispensed.

AT.390

Figure 20-12.–Dispenser and control.

The dispenser consists of three detachable sections which latch together to form a streamlined fairing. The center section contains the chaff package container, package holddown mechanism, and dispenser drive mechanism. Some models include a tape cutting assembly incorporated into the drive assembly. The nose and tail sections steamline the unit and detach to facilitate loading and servicing. (see fig. 20-13.)

Dispenser Control

The dispenser control (fig. 20-13) is installed within the aircraft either on the cockpit panel or in some convenient location, and contains all necessary controls for the operation of the dispensing system. The control consists of a DISP-RATE selector, a DISP-OFF-HOLD switch, and two panel light assemblies (connected to the aircraft cockpit panel light circuit). The DISP-RATE selector consists of a double wafer, a ten-position switch, a knob, and a plastic dial.

The DISP-OFF-HOLD control is a three-position toggle switch, spring loaded from HOLD to OFF positions. The DISP position controls the power to the dispensing mechanism, and the HOLD position actuates the package holddown mechanism within the dispenser.

Maintenance of the dispenser and the dispenser control and loading of the chaff materials within the dispenser are the responsibility of the Avionic's personnel.

The dispenser is approximately 117 inches long and 18.4 inches in diameter at its thickest part. The weight when empty is 86 pounds as compared to 210 pounds when loaded. The dispenser is loaded on a bomb rack, and receives operating power from the aircraft's 28-volt d-c supply through the dispenser control.

Figure 20-14 shows an internally mounted chaff dispenser. Two of these units are normally installed in one aircraft. Each dispenser unit consists of thirty discharge tubes joined together in parallel. One end of each tube is open and the other end is closed. The closed ends contain

13784

AT.392

Figure 20-14.–Chaff dispensers.

electrical contacts which operate an electrical initiator. The open ends are connected to a platform which serves as a mounting flange for the unit. The initiators serve as the propelling force to discharge the tubes load through the open end into the atmosphere.

This system has a control unit (not shown) that contains an intervalometer, a repeat cycle timer, and a time-delay relay for programming. The programing is accomplished by positioning two front panel mounted switches. One switch sets the desired sequential timing rate and the other sets the desired number of automatic sequenced ejections. Since this unit is mounted in an area not accessable to the pilot, these settings must be determined and adjusted before flight.

13785

An ON-OFF power switch to control the power to the system, a momentary "auto" switch for initiation of an automatic cycle dispensing operation, a momentary "single-fire" switch for initiation of a single-fire dispensing operation, and a solenoid-operated numerical counter to register each pulse from the dispensing set and read out the number of loads (chaff) remaining in the dispenser units are located in the cockpit for pilot control.

ECM TEST EQUIPMENT

Most of the test equipment used in the maintenance of ECM equipment is common to many other types of electronic equipment. The test equipment that may be considered special ECM test equipment comprises the RF signal generator(s) used to aline the ECM receivers.

Each generator used usually covers only one relatively small band of frequencies. Several generators are needed to maintain a complete set of ECM receivers. These RF generators (above VHF frequencies) produce various kinds of modulated RF signals. For example, continuous wave (straight RF), modulated continuous wave (audio-tone modulated), or pulse modulation may be selected. With the tone modulation, various tone frequencies may be selected. With the pulse modulation, various pulse widths and different pulse repetition frequencies may be selected.

13786

CHAPTER 21

INFRARED DETECTION

Infrared, or IR as it is sometimes called, is assuming increasing importance in missile guidance, target detection, fire control, communications, and mapping. Like radar, infrared was developed and used for military purposes during World War II. Unlike radar, however, the use of infrared has received little publicity. In some military applications, infrared energy has advantages over radar. Infrared, used as a medium of communications, is usually less susceptible to counterdetection and interference than is radar or visible light. Infrared equipment is generally less complex than radar equipment used for similar tasks.

ELECTROMAGNETIC SPECTRUM

IR is a form of electromagnetic energy, with certain characteristics identical to those of light and RF waves. Among these characteristics, some of the more important ones are reflection, refraction, absorption, and speed of transmission. Infrared waves differ from light, RF, and other electromagnetic waves only in wavelength and frequency of oscillation.

The frequency of IR ranges from approximately 300,000 megahertz to 400 million megahertz. Its place in the electromagnetic spectrum (fig. 21-1) is between visible light and the microwave region used for high definition radars. This part of the spectrum is usually discussed in terms of wavelength, and it is generally accepted that the IR spectrum lies between 0.72 and approximately 1,000 microns (1 micron equals 0.0001 centimeter).

The IR portion of the electromagnetic spectrum is frequently divided into the following three parts:

1. The near infrared (NIR) which extends from the visible region out to around 1.5 microns.
2. The intermediate infrared (IIR) which extends from 1.5 to 5.6 microns.
3. The far infrared (FIR) which extends from 5.6 microns to microwave frequencies.

Some confusion in terminology exists because infrared energy is so close to the visible range of wavelengths in the electromagnetic spectrum. Thus, it is not uncommon to hear references to "infrared light," although the term is inaccurate. Infrared waves are also loosely referred to as heat waves, because of the well-known fact that a solid object subjected to radiation by infrared energy undergoes an increase in temperature. Heat differs from infrared waves in much the same way that electricity differs from radio waves.

INFRARED RADIATION

All objects above absolute zero (0° K or -273° C or -460° F) emit infrared radiation. Radiation from any given object is emitted over a wide range of wavelengths, but it reaches a peak at one particular wavelength. This point is of considerable interest in military applications, as will be shown later. Detection of infrared energy depends on the contrast between IR from the source under consideration and the radiation emitted by the background. A cold object with a warm background has just as good target definition as a warm object with a cold background.

There are a number of advantages in using IR for target detection rather than some other form of electromagnetic transmission. Among these are the following:

13787

1. IR systems are passive.
2. Although IR systems can be confused, complete jamming is just about impossible.
3. Military targets are usually good sources of IR.
4. IR systems may be made smaller, lighter, less complex, and less expensive than other comparable systems.
5. IR systems have higher target resolution.

EMISSIVITY

One of the most useful concepts employed when working with IR is the "black body." A black body is defined as an object which absorbs all radiation incident on it. Conversely, the radiation emitted by a black body is the maximum possible for any given temperature. This black body is then a perfect absorber and

AQ.248

Figure 21-1.—Electromagnetic spectrum, showing different wavelength units used in different bands of the spectrum.

13788

radiator of IR at all temperatures and for all wavelengths.

In order to compare the radiation emitted by an actual source with that of a perfect radiator, the concept of emissivity is employed. Emissivity is defined as the ratio of the total radiation emitted by any object at any temperature (T) to the total radiation which would be emitted by an ideal black body at the same temperature. The emissivity of any object depends on the amount of energy its surface can absorb. If the surface absorbs most of the IR striking it, then it will emit a relatively high amount of radiation, and the emissivity of the object will be comparatively large. By the same reasoning, if the surface reflects most of the incident radiation, the object will have a relatively small emissivity. By definition, a black body has an emissivity of unity. Therefore, any other object will have an emissivity of less than one. Table 21-1 shows the emissivity of various surfaces.

Table 21-1.–Emissivities of various surfaces.

Surface	Emissivity
Black body	1.00
Lampblack	0.95
Painted	0.90
Steel, cold-rolled	0.60
Aluminum paint	0.25
Steel, stainless	0.09
Aluminum aircraft skin	0.08
Aluminum foil	0.04
Silvered mirror	0.02

Laws of Emissivity

The basic laws which describe the characteristics of IR were developed first for black body radiation, the ideal case, and then modified to describe the radiation from any source.

The most important parameter in determining the IR characteristics of any body is its temperature. As the temperature of an object changes, two specific changes in the IR characteristics take place: The wavelength where peak radiation occurs is shifted, and the total energy radiated varies with the fourth power of the temperature. These fundamental relationships are given by two laws which are discussed in the following paragraphs.

WIEN'S DISPLACEMENT LAW.–This law states that the wavelength at which maximum radiation occurs, λ_m is inversely proportional to the absolute temperature of the body. This can be expressed by

$$\lambda_m = \frac{K}{T}$$

where the wavelength is given in microns, and the constant (K) has a value (for a black body) of about 2,900. For example, a block of ice emits its peak energy at about 10 microns, while energy emitted from a jet aircraft engine peaks at about 3.5 microns. The relationship is shown in figure 21-2.

STEFAN-BOLTZMANN LAW.–This law states that the radiation intensity, E, is directly proportional to the fourth power of the absolute temperature, expressed as

$$E = \Sigma T^4$$

where E has dimensions of power per unit area, and Σ is the proportionality constant. In other words, if the temperature of an object is doubled, the radiation emitted from the object will be 16 times as much.

The Stefan-Boltzmann Law can be modified to include the emissivity factor; and by using the right units, the total radiation can be obtained by

$$E = \epsilon \Sigma T^4$$

where ϵ is the emissivity factor of the radiating surface.

A black body at an absolute temperature of 300°K (81° F) will radiate 46 milliwatts of power per square centimeter of its surface. A painted surface, such as the skin of a commercial airliner, at the same absolute temperature will radiate 41 milliwatts per square centimeter. If this aluminum aircraft skin were not painted, the emissivity factor would be considerably smaller, and the radiation would be less than 4 milliwatts of power per square centimeter. As mentioned previously, IR from a source will be distributed over a good part of the spectrum, but the maximum radiation occurs at some specific wavelength. Figure 21-3 shows the dis-

13789

AQ.249

Figure 21-2.–The wavelength of the peak radiation from a black body in relation to its temperature.

tribution of energy radiated from a black body at various temperatures.

As an example, IR from jet and rocket engine exhaust plumes is primarily due to the molecular excitation of water vapor and carbon dioxide which are characteristic byproducts of combustion. This molecular radiation peaks at 2.7 microns (due to water vapor and carbon dioxide) and 4.3 microns (due to carbon dioxide alone). In a practical situation, however, more usable radiation is obtained from the hot tailpipe and other heated surfaces.

TRANSMISSION CHARACTERISTICS

In military applications of IR systems, the transmitting medium is generally the atmosphere. The effect of the atmosphere on the transmission of IR is a very important factor in considering the overall effectiveness of the system.

Atmospheric Absorption

There are two primary causes of atmospheric attenuation: scattering by suspended solids, and absorption by free molecules. These two influences on the attenuation are additive, but the absorption is the most important factor.

The amount of scattering caused by particles depends on the relationship between the wavelength of the radiated energy and the size of the particles. If the wavelength involved is considerably shorter than the dimensions of the particles, then the scattering is just about independent of wavelength. Since this is generally the case in the IR spectrum, the attenuation due to scattering can be measured at one wavelength and then applied over a relatively wide band of wavelengths.

This technique does not work, however, with attenuation due to molecular absorption. The amount of absorption is closely connected with the wavelength. The two substances in the atmosphere which absorb the most radiation are water vapor and carbon dioxide. In both of these substances, there are several wavelength bands where the absorption is relatively large. This condition is caused by molecular resonance. (Each molecule has a "natural frequency" of vibration, or resonant frequency.)

The resonant frequencies of these molecules are in the infrared region, and their structure is such that this natural vibration creates an oscillation of electric charge in the molecules which increases the absorption. At low altitudes, where the atmosphere is more dense, this absorption is so great that in some wavelength bands the percentage of radiation transmitted drops rapidly to zero. Between these absorption bands are areas where the atmospheric attenuation is not so great. These transmission bands are called "windows." The transmission windows in the atmosphere are approximately as shown in table 21-2.

Figure 21-4 shows the transmission characteristics of the atmosphere at two different altitudes. It will be noted by reference to figure 21-4 that the 2.7 and 4.3 micron radiation readings from a jet exhaust plume occur at frequencies of high absorption. The radiation resulting from hot tailpipe surfaces is a function of tailpipe material and temperature, usually peaking at about 3.5 microns. This frequency is

13790

in the region of an atmospheric window or low absorption band. It will also be noted that the absorption bands are much narrower at high altitudes due to the thinner atmosphere. These absorption bands will, therefore, be of lesser consideration in the design of high altitude systems.

OPTICAL DEVICES

Because of the similarity between infrared and visible light, optical devices are usually employed to gather and focus the infrared radiation upon the detector. A simplified infrared optical arrangement is shown in figure 21-5. This illustration shows a simple optical system which could be used to focus IR radiation. The entire system is enclosed within a protective housing to protect the detector and optical system from the weather. The dome is a continua-

13792

tion of the protective housing and must be able to pass infrared radiation easily.

Typical materials from which domes are fabricated include glass, quartz, synthetic sapphires, germanium, and silicon. The transmission coefficient of the optical material is an important factor in the design of infrared equipment. For NIR, and generally for IIR, glass and quartz are satisfactory. Figure 21-6 shows that glass, quartz, and synthetic sapphires have excellent transmission characteristics in the visible and near infrared regions. They cut off sharply in the middle infrared region. Optical glass is completely opaque to wavelengths longer than 3 microns, quartz cuts off at 4 microns, and synthetic sapphire loses its transparency at wavelengths greater than 6 microns.

Germanium and silicon are semiconductor materials which are opaque to visible light and transparent throughout most of the near and middle infrared regions.

A wholly different type of optics is required for FIR. Single crystals of silver chloride, rolled flat, are satisfactory windows for the transmission of FIR. Sodium chloride (rock salt), grown in single crystals and cut and ground into a lens or window, is excellent. However, rock salt is highly soluble in water and must be protected from the atmospheric moisture. Therefore, rock salt is not practical to use as an IR dome material.

There are a number of problems involved in the design of IR optical systems. The material used must match the wavelength to which the detector will respond. Optical materials are generally weak physically, and many have a low resistance to high temperature and thermal shock. Chemical reactions and pressure will change the properties of some materials.

Another vital problem is that of system heating. If any part of the system becomes heated by energy it has absorbed, this energy will be reradiated at wavelengths that differ from those of the original radiation. If the detector is sensitive to these new wavelengths,

AQ.253

Figure 21-6.–Wavelength vs. transmission coefficient.

13793

this source which is much closer than the target will obscure the target or cause "ghost" images.

Attenuation in optical materials is primarily due to two things: surface reflections, usually overcome by antireflection coatings; and attenuation by the material. The latter is the more serious problem.

IR systems often have a chopping reticle in the principal focal plane. The chopper is generally a rotating disk with some clear and some opaque areas. Although a chopper is not absolutely necessary in a search system, it has several useful properties. The chopping rate furnishes a conveniently high carrier frequency for the electronic amplifiers. The reticle pattern can operate as a discriminator or filter. For example, it can be designed for the type of backgrounds expected in order to provide better differentiation of target and background.

Optical filters are used in IR instruments to isolate certain wavelength regions of interest, such as atmospheric windows, and to screen out undesired wavelengths. Three general types of filters are as follows:

1. Those which pass short waves.
2. Those which pass a particular band of waves.
3. Those which pass long waves.

DETECTORS

The most critical component of any IR system is the detector. The characteristics of the atmosphere and the source, if it is a military target, cannot be changed. Optical materials are somewhat standardized, as are display devices and control circuits. Although research and development in the last decade has resulted in some very good all-round detectors, it is still necessary to use care in choosing the proper one for a particular application.

Many variables must be considered in the choice of a detector. The characteristics of the radiation involved will determine which type of detector will best fit the needs of the system.

DETECTOR CHARACTERISTICS

In order to compare the relative merits of different detectors in different situations, it is necessary to introduce several parameters of detector operation. These parameters make it possible to discuss the characteristics of a particular detector in terms which can be applied to any detector.

Responsivity

When IR strikes a detector material, either photoelectric or thermal, a change takes place which produces an electrical output signal, indicating that the material has been exposed to IR. The amount of signal produced by each unit of input radiation intensity is called the responsivity (R) of the detector, and is expressed as

$$R = \frac{\text{output}}{\text{input}}$$

generally in volts per watt. Many factors influence the responsivity, such as temperature of the detector and source, detector area, spectral distribution of the radiation, detector time constant, etc.

Spectral Response

One important influence on the responsivity of a detector is the change in detector sensitivity with changes in the wavelength of received radiation. The spectral limit of responsivity is considered to be the wavelength where the responsivity is half that of its maximum value. Since the spectral response is a nonlinear characteristic, it must be known for each wavelength considered, and any discussion of values must include the details of the conditions involved.

Time Constant

In any IR scanning system, the time constant of the detector must be such that the detector can fully respond before the radiation intensity changes. The time constant is considered to be the time required for the detector to develop 63 percent of its maximum output signal. The maximum scanning rate is dependent upon this time constant.

13794

OBJECTIVE: To learn when and how to use three-view drawings.

FIG. 1

RELATED INFORMATION:

Fig. 1 shows the difference between a pictorial drawing of an object and a mechanical drawing shown in orthographic projection. Part A of Fig. 1 is a pictorial drawing of an object and indicates only its general shape and size, as seen from one direction. It does not show the sizes of various parts of the object in their true ratio to one another.

Part B of Fig. 1 is a mechanical drawing shown in orthographic projection. Though not complete, since the dimensions are not shown, it gives important information needed by workmen. It represents the object as it actually is, not as it appears to the eye. In order to show this, mechanical drawings often show three views of the object: front, top, and right side, as in B of Fig. 1.

1377

Noise

Noise exists in any circuit that carries current. Most outside noises can be eliminated or drastically reduced by shielding and proper design, but thermal noise is an ever-present problem.

Power supplies employed with IR detectors must be extremely well filtered. Since the IR radiation received by the detector is very small, noise of any appreciable amount could be sufficient to mask weak IR signals or cause false targets. Transistors, for an example, are useless in IR amplifiers because of their inherent noise characteristics.

Many different types of noise are generated within IR systems. Among these, the most important are as follows:

1. Current noise, caused by bias currents within the detector.

2. Johnson (thermal) noise, caused by thermal fluctuations in the detector material.

At low bias voltages, current noise is negligible and the output noise voltage consists almost entirely of Johnson noise. The current noise increases linearly with bias voltages and may eventually become the primary source of noise.

NOISE EQUIVALENT POWER.–Another useful and important detector parameter is the noise equivalent power (NEP) of a detector. NEP is the radiation power in watts which must strike a detector to produce a signal response from the detector equal to the noise output (in other words, signal to noise ratio of 1) over a reference bandwidth.

When comparing two different IR detectors, the one with the lower NEP has the higher useful sensitivity. Since this tends to be confusing, another parameter is used–the detectivity. This figure is simply the reciprocal of the given NEP of a detector, so that the higher detectivity a cell has, the higher is its useful output. For example, a detector with an NEP of 4.0×10^{-9} will have a detectivity of 2.5×10^{8}.

The best IR detector would be one having the greatest possible responsivity, the widest possible spectral response within the frequency band of interest, and the lowest possible NEP (or highest possible detectivity). A properly chosen detector, with the necessary operating conditions, might have a maximum range of 90 miles with a signal to noise ratio of 5 from a 1 square meter target at 300° Kelvin. This range is equivalent to an ability to detect IR emitted by a cubic inch of ice at 3 miles.

PHOTODETECTORS

The three major types of photodetectors are photoconductive, photovoltaic, and photoemissive. Signal to noise ratio of the detector is the limiting factor in determining its effectiveness. These are used in the near infrared spectrum.

Photoconductors use a semiconductor crystal that absorbs the photon energy from the radiation which strikes the surface of the crystal, changing its resistance or conductivity. Quite a number of materials have been used for this type of photodetector, including lead sulfide, lead telluride, lead selenide, cadmium sulfide, and many others. Gold-doped germanium has been established as a good detector material, but some difficulties, such as the long time constant, must be considered.

Photovoltaic cells are similar to solar cells. These are semiconductors with a high resistance photosensitive barrier between the two layers. When exposed to IR, this cell builds up a potential difference between the two layers.

Photoemissive cells operate on the principle that electronic emission is caused by exposing the cathode to IR. In this type of emission, the number of electrons emitted depends on the intensity of the IR striking the cathode.

THERMAL DETECTORS

Thermal detection is accomplished by sensing the change in temperature of the detector material as a result of IR striking its surface. There are three different types of sensing elements employed in modern detectors to sense this temperature change. These are as follows:

1. The thermopile, which is a series combination of several thermocouples.

2. Bolometers, which sense the change in resistance of the detector material.

3. Pneumatic cells, which use the expansion of a gas as an indicator.

13795

Thermocouple

One of the basic heat detectors is the thermocouple. When two dissimilar metals such as iron and copper are joined together and heat is applied to the junction, a measureable voltage will be generated between them. Figure 21-7 shows a basic thermocouple.

The voltage difference between two metals is quite small, but the sensitivity can be increased to a point at which the thermocouple becomes useful as a detector of IR. The increase in sensitivity is obtained by connecting or stacking a number of thermocouples in series, so that they form what is known as a thermopile. The complete thermopile action is similar to that obtained when a number of flashlight cells are connected in series; that is, the output of each individual thermocouple is added to the output of the others. Thus, ten thermocouples, with individual output voltages of 0.001 volt, would have a total output of 0.010 volt when connected in series.

The effective sensitivity of a thermopile can be further increased by mounting it at the focal point of a parabolic reflector. When this method is used, IR given off by the target is focused on the thermopile by the reflector.

Bolometers

A bolometer is a very sensitive material whose resistance will vary, depending on the amount of IR to which it is exposed. There are two main classes of bolometers – barretters and thermistors.

AQ.254

Figure 21-7.–Thermocouple.

AQ.255

Figure 21-8.–Various thermistors.

A barretter consists of a short length of very fine wire (usually platinum) which has a positive temperature coefficient. (A substance has a positive temperature coefficient if its resistance increases with temperature, and a negative coefficient if its resistance decreases with an increase in its temperature.)

The thermistor is a type of variable resistor made of semiconducting material, such as oxides of manganese, nickel, cobalt, selenium, and copper. The thermistor has a negative temperature coefficient of resistance. Thermistors are made in the form of beads, disks, rods, and flakes, some of which are shown in figure 21-8.

The heat sensitive materials of thermistors are mixed in various proportions to provide the specific characteristics of resistance versus temperature necessary for target detection.

Figure 21-9 shows the change in resistance which can be produced in a typical thermistor material and in a barretter. This comparison shows that the thermistor has the steeper tem-

13796

perature coefficient of resistance curve, and therefore is the more sensitive of the two sensors.

One simple type of infrared detector consists of two thin strips of platinum which are used to form two arms of a Wheatstone bridge. To increase the thermal sensitivity of the strips, each is blackened on one side. The IR to be measured is applied to one of the strips, and is absorbed by its blackened surface. As the strip absorbs heat, its resistance changes and unbalances the bridge. The imbalance causes a change in current produced by an external voltage applied to the input terminals of the bridge.

A device of this kind is shown in figure 21-10. It consists of four nickel strips supported by mounting bars, which have electrical leads attached to them. A silvered parabolic reflector

AQ.257

Figure 21-10.–Infrared detecting device.

(mirror) is used to focus the IR on the nickel strips. The change of resistance in the strips produces unbalanced conditions in the bridge circuit which can be used to produce correction signals.

Pneumatic Cell

Another unique infrared detector is the pneumatic cell or GOLAY detector shown in figure 21-11. This detector is actually a miniature heat engine.

Infrared energy entering the window causes expansion of a volume of gas located between the reflecting diaphragm and the window. The lamp at the after end of the detector emits a light beam which is focused by the lens and then passes through the grid and onto the reflecting diaphragm. The expansion and contraction of the gases between the window and diaphragm will cause the diaphragm to change its shape in response to changes in the amount of infrared energy entering the window.

Changes in shape of the diaphragm will cause its light-reflective properties to vary accordingly, modulating its light output. The light reflected from the diaphragm will then pass back through the grid which is designed to in-

AQ.256

Figure 21-9.–Comparison of thermistor and barretter sensitivity.

13797

AQ.258

Figure 21-11.—Golay detector.

tensify the variations of the reflected light. After passing through the grid, some of the light strikes the mirror and is reflected to a photocell of high sensitivity (not shown in the figure). The modulated output of the photocell is a voltage proportional to the intensity of the IR entering the window.

The Golay detector has the most rapid response of any infrared detector, but it can operate only when radiant heat is received intermittently. An optical chopper may be used to interrupt the flow of IR to the cell periodically. Another advantage of the Golay detector is its extremely wide bandwidth, making it a very good choice for use in IR spectrum analysis.

APPLICATIONS

Military and industrial applications of IR have grown in number considerably in the last decade. A complete discussion of all applications would be beyond the scope of this manual. However, some of the systems and concepts applicable to military situations are discussed in the following paragraphs.

MILITARY USES OF INFRARED

Infrared devices found their first military uses during World War II as a snooperscope which operated in total darkness and outlined enemy troops by the heat radiated from their bodies. A rifle with a device known as the sniperscope made it possible to see a target in total darkness and fire with normal accuracy without the enemy becoming aware of one's presence.

Since infrared is invisible but behaves much like visible light (that is, it can be reflected and controlled in a beam pattern), it has served as a means of communication for specific wartime purposes. Development of equipment which would receive the invisible light was the foundation for the design and successful use of some highly important weapons. Infrared, when used for short-range communication between sea-level stations, such as ships, affords excellent security. Infrared rays are limited to line of sight, and are rapidly attenuated at sea level; thus, IR acts in favor of security for short-range communications. Military use of infrared for communications therefore requires a powerful source that can be modulated and sensitive receivers for detecting the modulated source. Such sources and receivers have been developed for near infrared energy.

Infrared is used in photography as it is effective against camouflaged targets. Night photography using infrared can produce a better visual presentation of terrain than the best mapping radar.

Infrared has invaded the navigation field. Groundspeed indicators are being developed that will compete with Doppler radar. Anticollision circuits are under experimentation.

IR is also used in image forming devices, thermal or ship detection, and infrared radar. The portable infrared detector (PID) is a passive

13798

far infrared (FIR) equipment used for the detection of personnel, vehicles, tanks, small boats, and ships. It detects the difference in temperature between a body and its immediate background and provides an audible signal output. A larger far infrared system for ship detection is the stabilized ship detector (SSD). This provides a permanent record of the true bearing of all targets that are detected within the angle scanned. Infrared radar uses a pulsed IR source and receives reflected IR energy as in microwave radar.

Infrared has excellent application to guided missiles. Military targets, such as ships, factories, and aircraft, are normally warmer than their surroundings. The presence of these targets may be detected by the heat radiation they emit. The radiation of heat at lower temperatures is particularly important in the passive detection of surface targets, since there is no economical way by which the enemy can camouflage his self-radiated heat.

The Felix bomb was the first guided missile to utilize IR. It was automatically guided by an infrared homing device in the nose of the bomb. The Felix bomb was thoroughly tested and declared reliable and adequate for operational use, but World War II ended before it could be used under combat conditions. This opened the way to a new and different method of guidance, infrared homing.

Homing guidance systems control the path of the missile by a device in the missile that reacts to some distinguishing feature of the target. They are the most accurate of all guidance systems. Homing systems are divided into the following three types, depending upon the source of target radiations:

1. Active homing–both the source which illuminates the target and the receiver which detects the echoes are carried in the missile.
2. Semiactive homing–the target is illuminated by some source outside the missile and the missile receiver utilized the target reflections.
3. Passive homing–the missile receiver detects the natural radiation of the target.

Active and semiactive types generally use radar, whereas passive types use heat or light, or in some cases, home on a radio or radar transmitter.

The Sidewinder is probably the simplest and cheapest of all guided missiles. It uses an infrared homing system and is designed to destroy high-performance aircraft from sea level to about 50,000 feet.

The experimental Midas satellite, which was launched by the United States, employs infrared principles. It is equipped with an infrared scanning device capable of instantaneous spotting and reporting of the launching of a hostile ballistic missile. It is expected to provide complete and constant scanning of the earth's surface. Flashing an alarm of the blast-off of enemy missiles, would give the United States 30 minutes to prepare for nuclear bombardment.

While it is unlikely that radar will ever be entirely replaced by IR, it is already an established fact that IR possesses certain advantages over radar. It is expected that radar and IR will work as a team in many applications, such as fire control, guidance, and even search.

13798

APPENDIX I
FORMULAS

Ohm's Law for D-C Circuits

$$I = \frac{E}{R} = \frac{P}{E} = \sqrt{\frac{P}{R}}$$

$$R = \frac{E}{I} = \frac{P}{I^2} = \frac{E^2}{P}$$

$$E = IR = \frac{P}{I} = \sqrt{PR}$$

$$P = EI = \frac{E^2}{R} = I^2R$$

Resistors in Series

$$R_T = R_1 + R_2 + \ldots$$

Resistors in Parallel

Two resistors

$$R_T = \frac{R_1R_2}{R_1 + R_2}$$

More than two

$$\frac{1}{R_T} = \frac{1}{R_1} + \frac{1}{R_2} + \frac{1}{R_3} + \ldots$$

RL Circuit Time Constant

$$\frac{L \text{ (in henrys)}}{R \text{ (in ohms)}} = t \text{ (in seconds), or}$$

$$\frac{L \text{ (in microhenrys)}}{R \text{ (in ohms)}} = t \text{ (in microseconds)}$$

RC Circuit Time Constant

R (ohms) x C (farads) = t (seconds)

R (megohms) x C (microfarads) = t (seconds)

R (ohms) x C (microfarads) = t (microseconds)

R (megohms) x C (micromicrofarads) = t (microseconds)

Capacitors in Series

Two capacitors

$$C_T = \frac{C_1C_2}{C_1 + C_2}$$

More than two

$$\frac{1}{C_T} = \frac{1}{C_1} + \frac{1}{C_2} + \frac{1}{C_3} + \ldots$$

Capacitors in Parallel: $C_T = C_1 + C_2 + \ldots$

Capacitive Reactance: $X_C = \frac{1}{2\pi fC}$

Impedance in an RC Circuit (Series)

$$Z = \sqrt{R^2 + (X_C)^2}$$

Inductors in Series

$L_T = L_1 + L_2 + \ldots$ (No coupling between coils)

Inductors in Parallel

Two inductors

$L_T = \frac{L_1L_2}{L_1 + L_2}$ (No coupling between coils)

More than two

$\frac{1}{L_T} = \frac{1}{L_1} + \frac{1}{L_2} + \frac{1}{L_3} + \ldots$ (No coupling between coils)

Inductive Reactance

$$X_L = 2\pi fL$$

Q of a Coil

$$Q = \frac{X_L}{R}$$

13801

13800

Impedance of an RL Circuit (Series)

$$Z = \sqrt{R^2 + (X_L)^2}$$

Impedance with R, C, and L in Series

$$Z = \sqrt{R^2 + (X_L - X_C)^2}$$

Parallel Circuit Impedance

$$Z = \frac{Z_1 Z_2}{Z_1 + Z_2}$$

Sine-Wave Voltage Relationships

Average value

$$E_{ave} = \frac{2}{\pi} \times E_{max} = 0.637E_{max}$$

Effective or r. m. s. value

$$E_{eff} = \frac{E_{max}}{\sqrt{2}} = \frac{E_{max}}{1.414} = 0.707E_{max}$$
$$= 1.11E_{ave}$$

Maximum value

$$E_{max} = \sqrt{2}\,(E_{eff}) = 1.414E_{eff}$$
$$= 1.57E_{ave}$$

Voltage in an a-c circuit

$$E = IZ = \frac{P}{I \times P.F.}$$

Current in an a-c circuit

$$I = \frac{E}{Z} = \frac{P}{E \times P.F.}$$

Power in A-C Circuit

Apparent power: $P = EI$

True power: $P = EI \cos\theta = EI \times P.F.$

Power Factor

$$P.F. = \frac{P}{EI} = \cos\theta$$

$$\cos\theta = \frac{\text{true power}}{\text{apparent power}}$$

Transformers

Voltage relationship

$$\frac{E_p}{E_s} = \frac{N_p}{N_s} \text{ or } E_s = E_p \times \frac{N_s}{N_p}$$

Current relationship

$$\frac{I_p}{I_s} = \frac{N_s}{N_p}$$

Induced voltage

$$E_{eff} = 4.44 \times BAfN \times 10^{-8}$$

Turns ratio

$$\frac{N_p}{N_s} = \sqrt{\frac{Z_p}{Z_s}}$$

Secondary current

$$I_s = I_p \times \frac{N_p}{N_s}$$

Secondary voltage

$$E_s = E_p \times \frac{N_s}{N_p}$$

Three-Phase Voltage and Current Relationships.

With wye connected windings

$$E_{line} = \sqrt{3}(E_{coil}) = 1.732E_{coil}$$

$$I_{line} = I_{coil}$$

With delta connected windings

$$E_{line} = E_{coil}$$

$$I_{line} = 1.732I_{coil}$$

13801

13800

With wye or delta connected winding

$$P_{coil} = E_{coil} I_{coil}$$

$$P_t = 3P_{coil}$$

$$P_t = 1.732 E_{line} I_{line}$$

(To convert to true power multiply by $\cos\theta$)

Resonance

At resonance

$$X_L = X_C$$

Resonant frequency

$$F_o = \frac{1}{2\pi\sqrt{LC}}$$

Series resonance

$$Z \text{ (at any frequency)} = R + j(X_L - X_C)$$

$$Z \text{ (at resonance)} = R$$

Parallel resonance

$$Z_{max} \text{ (at resonance)} = \frac{X_L X_C}{R} = \frac{X_L{}^2}{R}$$

$$= QX_L = \frac{L}{CR}$$

Band width

$$\Delta = \frac{F_o}{Q} = \frac{R}{2\pi L}$$

Tube Characteristics

Amplification factor

$$\mu = \frac{\Delta e_p}{\Delta e_g} \text{ (i_p constant)}$$

$$\mu = g_m r_p$$

A-c plate resistance

$$r_p = \frac{\Delta e_p}{\Delta i_p} \text{ (e_g constant)}$$

Grid-plate transconductance

$$g_m = \frac{\Delta i_p}{\Delta e_g} \text{ (e_p constant)}$$

Decibels

NOTE: Wherever the expression "log" appears without a subscript specifying the base, the logarithmic base is understood to be 10.

Power ratio

$$db = 10 \log \frac{P_2}{P_1}$$

Current and voltage ratio

$$db = 20 \log \frac{I_2 \sqrt{R_2}}{I_1 \sqrt{R_1}}$$

$$db = 20 \log \frac{E_2 \sqrt{R_1}}{E_1 \sqrt{R_2}}$$

NOTE: When R_1 and R_2 are equal they may be omitted from the formula. When reference level is one milliwatt

$$dbm = 10 \log \frac{P}{0.001} \text{ (when P is in watts)}$$

Synchronous Speed of Motor

$$r.p.m. = \frac{120 \times \text{frequency}}{\text{number of poles}}$$

138023

13802

Comparison of Units in Electric and Magnetic Circuits

	Electric circuit	Magnetic circuit
Force.	Volt, E, or e.m.f.	Gilberts, F, or m.m.f.
Flow	Ampere, I	Flux, Φ , in maxwells
Opposition.	Ohms, R	Reluctance, $\mathcal{R}$
Law.	Ohm's law, $I = \frac{E}{R}$	Rowland's law, $\Phi = \frac{F}{\mathcal{R}}$
Intensity of force	Volts per cm. of length.	$H = \frac{1.257IN}{L}$, gilberts per centimeter of length.
Density.	Current density—for example, amperes per cm^2.	Flux density—for example, lines per $cm.^2$, or gausses.

13803

APPENDIX II

SYMBOLS

(WHEN CAPACITOR ELECTRODE IDENTIFICATION IS NECESSARY, THE CURVED ELEMENT SHALL REPRESENT THE OUTSIDE ELECTRODE IN FIXED PAPER-DIELECTRIC AND CERAMIC-DIELECTRIC, THE NEGATIVE ELECTRODE IN ELECTROLYTIC CAPACITORS, THE MOVING ELEMENT IN VARIABLE AND ADJUSTABLE CAPACITORS, AND THE LOW POTENTIAL ELEMENT IN FEED-THROUGH CAPACITORS.)

NATIONAL BUREAU OF STANDARDS-1963-A

APPENDIX III

LAWS OF EXPONENTS

The International Symbols Committee has adopted prefixes for denoting decimal multiples of units. The National Bureau of Standards has followed the recommendations of this committee, and has adopted the following list of prefixes:

Numbers	Powers of ten	Prefixes	Symbols
1,000,000,000,000	10^{12}	tera	T
1,000,000,000	10^{9}	giga	G
1,000,000	10^{6}	mega	M
1,000	10^{3}	kilo	k
100	10^{2}	hecto	h
10	10	deka	da
.1	10^{-1}	deci	d
.01	10^{-2}	centi	c
.001	10^{-3}	milli	m
.000001	10^{-6}	micro	u
.000000001	10^{-9}	nano	n
.000000000001	10^{-12}	pico	p
.000000000000001	10^{-15}	femto	f
.000000000000000001	10^{-18}	atto	a

To multiply like (with same base) exponential quantities, add the exponents. In the language of alegebra the rule is $a^m \times a^n = a^{m+n}$

$$10^4 \times 10^2 = 10^{4+2} = 10^6$$

$$0.003 \times 825.2 = 3 \times 10^{-3} \times 8.252 \times 10^2$$

$$= 24.756 \times 10^{-1} = 2.4756$$

To divide exponential quantities, subtract the exponents. In the language of algebra the rule is

$$\frac{a^m}{a^n} = a^{m-n} \text{ or}$$

$$10^8 \div 10^2 = 10^6$$

$$3,000 \div 0.015 = (3 \times 10^3) \div (1.5 \times 10^{-2})$$

$$= 2 \times 10^5 = 200,000$$

To raise an exponential quantity to a power, multiply the exponents. In the languague of algebra $(x^m)^n = x^{mn}$.

$$(10^3)^4 = 10^{3x4} = 10^{12}$$

$$2,500^2 = (2.5 \times 10^3)^2 = 6.25 \times 10^6 = 6,250,000$$

Any number (except zero) raised to the zero power is one. In the language of algebra $x^0=1$

$$x^3 \div x^3 = 1$$

$$10^4 \div 10^4 = 1$$

Any base with a negative exponent is equal to 1 divided by the base with an equal positive exponent. In the language of algebra $x^{-a}=\frac{1}{x^a}$

$$10^{-2} = \frac{1}{10^2} = \frac{1}{100}$$

$$5a^{-3} = \frac{5}{a^3}$$

$$(6a)^{-1} = \frac{1}{6a}$$

To raise a product to a power, raise each factor of the product to that power.

$$(2 \times 10)^2 = 2^2 \times 10^2$$

$$3,000^3 = (3 \times 10^3)^3 = 27 \times 10^9$$

To find the nth root of an exponential quantity, divide the exponent by the index of the root. Thus, the nth root of $a^m = a^{m/n}$.

$$\sqrt{x^6} = x^{6/2} = x^3$$

$$\sqrt[3]{64 \times 10^3} = 4 \times 10 = 40$$

199

13812

APPENDIX IV

GREEK ALPHABET

Name	Capital	Lower Case	Designates
Alpha	A	α	Angles, coefficient of thermal expansion.
Beta.	B	β	Angles, flux density.
Gamma.	Γ	γ	Conductivity.
Delta	Δ	δ	Variation of a quantity, increment.
Epsilon.	E	ε	Base of natural logarithms (2.71828).
Zeta.	Z	ζ	Impedance, coefficients, coordinates.
Eta	H	η	Hysteresis coefficient, efficiency, magnetizing force.
Theta	Θ	θ	Phase angle.
Iota	I	ι	
Kappa	K	κ	Dielectric constant, coupling coefficient, susceptibility.
Lambda	Λ	λ	Wavelength.
Mu.	M	μ	Permeability, micro, amplification factor.
Nu	N	ν	Reluctivity.
Xi	Ξ	ξ	
Omicron	O	ο	
Pi	Π	π	3.1416
Rho	P	ρ	Resistivity.
Sigma.	Σ	σ	Summation symbol (cap).
Tau	T	τ	Time constant, time-phase displacement.
Upsilon.	Υ	υ	
Phi	Φ	φ	Angles, magnetic flux.
Chi	X	χ	
Psi	Ψ	ψ	Dielectric flux, phase difference.
Omega	Ω	ω	Ohms (capital), angular velocity (2 π f).

ABSTRACT - Issued by the Instructional Materials Laboratory of the Department of Practical Arts and Vocational-Technical Education of the University of Missouri in cooperation with the Vocational Education Division of the State of Missouri, this teaching guide is for instructor and student use in vocational agriculture classes. The material is designed for use over one semester (90 days), and is the basic course for a later series dealing with tractors and machinery. The contents are divided into 15 units, with each unit containing several problem sheets. Most sheets contain the stated problem area, the specific problem, the job title, study questions, a summary of the information, teaching suggestions, and references. A list of suggested prime references, a list of supplemental references, a tool list, and addresses of several companies are included. (GEB)

Preface

This course is designed as a special vocational agriculture course to be taught as a semester course. This course is the basic course to a later series of courses dealing with tractors and machinery. It is assumed that juniors and seniors would be enrolled in the course. It is designed to operate most effectively in a class of about 10 students.

The references listed on the following page are considered the prime references necessary to teach this semester course. Supplemental references can be found at the end of the teaching unit.

The demonstration lesson plans are designed to be used with the Briggs and Stratton six and eight cubic inch engines. However, many of the procedures used will be the same for most other gas engines.

There are numerous films and other teaching materials available from various small engine companies which are not listed here but would be quite helpful. It may be possible to have representatives from various related companies help out in some phases of this course.

Curtis R. Weston

13831

Problem Area: Small Gas Engines

Problem: Introduction and History

Job: Construction of the Gasoline Engine

Motivation: Imagine your farm at home with no internal combustion engines. How many think they understand how an engine works? How often do they need some kind of attention? How many know how to do all they need?

Study Questions:

1. Make a list of internal combustion engines you have at home.
2. Why is a steam engine or turbine not an internal combustion engine?
3. When was the first successful internal combustion engine made?
4. How can the burning of gasoline in an engine create a force?
5. What are the main parts necessary to internal combustion engines?
6. What are the three main kinds of internal combustion engines?
7. What are the differences between the 3 kinds?
8. For what is each kind most generally used?
9. What sequence of events is necessary in any internal combustion engine?

Summary of Information:

1. Make a class survey list on the board to determine kind, sizes, and types most common.
2. The combustion takes place outside the working parts and is transferred in while in the internal combustion the working parts move as a direct result of the force created.
3. A. In 1680 Huygens of Holland tried to make an engine run on gun powder but was unsuccessful.

   B. 1860 - Etienne Lenoir of France made the first successful model.

   C. 1862 - De Rochas of France set forth principles of the 4 stroke cycle.

   D. 1876 - Otto of Germany made the first successful 4 stroke cycle engine. It burned illuminating oil.

13832

13831

E. 1885 - A carburetor was developed so that gasoline could be used.

4. When the combustion takes place expansion always results.

5. Pistons, crankshaft, carburetor, valves, cylinder block.

6. Two stroke cycle and four stroke cycle and diesel.

7. Two stroke - fires every time the piston comes up,

less working parts.

Four stroke - fires every other time the piston comes up,

requires valves and a camshaft.

Diesel - burns low grade fuel,

doesn't use a spark plug ignition system.

8. 2 stroke cycle - small equipment, chainsaws, boat motors, lawnmowers.

4 stroke cycle - tractors, trucks, cars, lawnmowers.

Diesel - tractors and trucks. Large equipment.

9. A. Fill the cylinder with an explosive mixture.

B. Compress this mixture into a smaller space.

C. Ignite the mixture or cause it to explode.

D. Utilize the explosive or expansive force for power production.

E. Remove the burned out mixture from the cylinder.

Ref. Purvis, pages 9-16.

SLIDE BRACKET

Problem Area: Small Gas Engines

Problem: Principles of Engine Operation

Job: Definition of Terms

Motivation: How many moving parts of an engine can you name? Engines are rated by displacement, stroke, bore, compression ratio, and horsepower. Can you explain and figure each of these?

Study Questions:

1. What is the function of each of the following parts: a. piston, b. cylinder, c. piston pin (wrist pin), d. connecting rod, e. crankshaft, f. flywheel, g. valve, h. camshaft.

2. What is meant by compression? What is the effect of high compression?

3. What is the stroke?

4. What is the bore?

5. How can you figure displacement?

6. How is the compression ratio figured?

7. What are the methods of determining horsepower?

8. What is meant by torque? How is it measured?

9. What is the combustion chamber?

Summary of Information:

1. A. Piston - to receive the force of expansion from combustion.

   B. Cylinder - encases the piston allowing it to move up and down.

   C. Piston pin (wrist pin) - connects the piston to the connecting rod.

   D. Connecting rod - connects the piston to the crankshaft.

   E. Crankshaft - changes the reciprocating motion to circular motion

38643833

F. Flywheel - cuts down on vibration of the crankshaft and makes it run at an even speed.

G. Valve - opens and closes to let gases in or out of the combustion chamber.

H. Camshaft - opens valves at the proper times.

2. Compression is the pressure built up in the cylinder above the piston. High compression gets more power.

3. The stroke is the movement of the piston in the cylinder.

4. The bore is the diameter of the cylinder.

5. Stroke X (pi) X r^2 X number of cylinders

6. The compression ratio is determined by comparing the volume above the piston at top dead center to the volume at bottom dead center.

7. By a brake force - "Prony Brake". Dynamometer - energy transferred in a revolving armature or paddle wheel. Indicate HP - force of expanding gases HP - 33,000 lbs. moved 1 foot in 1 minute.

8. Turning effort. Measured in foot pounds. Force measured at a point 1 foot from the center of the drive shaft.

9. The area above the cylinder in which the firing and burning of gas takes place.

Ref. Purvis, pages 16-30.

Teaching Suggestions: Have samples of each part discussed. Use sample problems for figuring compression and displacement. Have students learn to work these out. Have students work out problems figuring horsepower with torque and time given.

13835

Problem Area: Small Gas Engines

Problem: Principles of Engine Operation

Job: Engine Construction

Motivation: Why do some people like one engine brand better than another.

Study Questions:

1. What properties must a cylinder wall possess.
2. How should bearing surfaces be made?
3. How can warpage be a problem?
4. How must the moving parts fit together?
5. What are the types of head design?
6. Why is aluminum used for engine blocks and heads?

Summary of Information:

1. Cylinder walls must be hard, tough and smooth. (Figure a problem to illustrate how far a piston travels in a cylinder in an hour of running time.)
2. Bearing surfaces should be hard and smooth. The amount of contact affects wear and friction.
3. Blocks or head may warp causing cylinder to be out of round, cause cracking, or leaking. This may be caused by improper casting and manufacture, but more likely by overheating, or uneven tightening of bolts.
4. All moving parts should fit precisely; even on all sides, enough clearance to reduce friction yet tight enough to limit slack or knock. Sleeve bearing surfaces should have slack from side to side to allow for free movement.

5

T-Head L-Head F-Head I-Head

Figure I

13836

6. It transfers heat quickly to the outside to be taken up by the cooling system. Aluminum has good wearing properties and is light in weight.

Ref. Purvis, pages 39-48.

Teaching Suggestions: If possible have parts for exhibit that are improperly fitted, warped, scored, or cracked. Do a demonstration showing heat transfer of aluminum and iron. Get 2 pieces the same size and put a piece of wax on the end of each, then heat the other end.

13837

Problem Area: Small Gas Engines

Problem: Principles of Engine Operation

Job: 2 Stroke Cycle

Motivation: Why are chainsaws, boat motors, 2 stroke cycle? How many could recognize a 2 stroke cycle engine by observing the external structure. How many could recognize it if it were taken apart?

Study Questions:

1. What is meant by the term "2 stroke cycle"?

2. What are the advantages of this type?

3. What are the disadvantages?

4. Explain what takes place during one cycle of the engine.

5. What keeps the incoming gases from going out the exhaust when it is at the bottom of the stroke?

6. Does a 2 stroke cycle engine need a carburetor? A spark plug? A valve? A camshaft assemble?

7. Make a diagram of a 2 stroke cycle engine near the top of the stroke going down and one near the bottom of the stroke going up. Label parts and explain.

Summary of Information:

1. It fires after 2 strokes. In otherwords fuel injection, exhaustion, compression, and ignition all take place in 2 strokes so that it fires every time the piston comes to the top.

2. More power per pound. Less working parts, less expensive to buy, and less vibration on a single cylinder engine.

3. Fuel mixture is controlled with some difficulty; power and speed are difficult to control; cooling and lubrication are difficult; less efficient and some what harder to start.

4. Use a mock-up engine or a cutaway model to show 2 cycle principle. On the upward stroke, gasoline vapor is pulled into the crankcase and the mixture in the cylinder is compressed. Just before top dead center ignition takes place. On the downward stroke, gases in the crankcase are compressed. At a point near the bottom the exhaust port is open. A little later the intake port from the crankcase is open. The gasoline air mixture rushes in from the crankcase and waste gases go out the exhaust port.

13838

5. There is a deflector on top of the piston.

6. Carburetor - yes. Spark plug - yes. Valve assembly - no.

7. Two-Cycle Engine Operation

Figure 2 Courtesy of Lawson Power Products

Ref. Purvis, pages 12-17.

Teaching Suggestions: Use a cutaway engine or a wooden mock-up of a 2 cycle engine. Use charts. Use a piston to show the deflector.

13839

Problem Area: Small Gasoline Engines

Problem: Principles of Engine Operation

Job: Four Stroke Cycle Engines

Motivation: What type of internal combustion engines do most cars have? Why?

Study Questions:

1. What is meant by the term "4 stroke cycle"?
2. What are the advantages of the 4 stroke cycle?
3. What are the disadvantages?
4. Make 4 drawings, each indicating what takes place during each stroke in the complete cycle and explain.
5. What is another name for the 4 stroke cycle?
6. Does a 4 stroke cycle engine need a carburetor? A spark plug? A valve and camshaft assembly?

Summary of Information:

1. The piston makes 4 strokes: 2 up and 2 down to accomplish all phases necessary for combustion power.
2. Lasts longer. Greater efficiency of fuel. Better lubrication.
3. Heavier per horsepower. More working parts to go wrong.
4.

Intake Stroke | Compression Stroke | Power Stroke | Exhaust Stroke

Figure 3

13840

5. Otto cycle, named after the inventor

6. Carburetor - yes. Spark plug - yes. Valve assembly - yes.

Ref. Purvis, pages 12-15; Briggs and Stratton General Theories, pages 3-7.

Teaching Suggestions: Use a cutaway or a wooden mock-up of a single cylinder 4 stroke cycle engine. Use charts.

13841
13842

Problem Area: Small Gasoline Engines

Problem: Principles of Engine Operation

Job: Diesel Engines

Motivation: How many of you have a diesel engine at home? Why do you have a diesel instead of a gasoline engine? Diesels come in sizes from the model airplane to an ocean liner, with a bore of several feet.

Study Questions:

1. How many strokes are in one cycle of the diesel engine?

2. What is the compression ratio of a diesel as compared to a gasoline engine?

3. What ignites the fuel?

4. What fuel is used? Why couldn't a gasoline-air mixture work?

5. Which of the following parts does a diesel have? a. carburetor, b. spark plug, c. valve.

6. What is the function of the injection system?

7. What mechanism does the 2 cycle diesel engine have that the 2 cycle gasoline engine does not have?

Summary of Information:

1. Either 2 or 4.

2. Much higher. About 18 to 1 while 10 to 1 is high for gasoline.

3. The heating which results from the compressing process.

4. Low grade petroleum. Gasoline would ignite before the piston reached the top of the cylinder.

5. Valves - some have a glow plug for starting.

6. a. Measure or meter the quantity of fuel entering each cylinder.

   b. Provide enough pressure to force the fuel into the cylinder at peak compression.

   c. Inject the fuel at the precise time it can burn to best advantage.

   d. Atomize the fuel as completely as possible at the instant of injection.

13841
13842

7. A blower to force air into the combustion chamber, and exhaust valves.

Ref. Purvis, pages 104-110.

Problem Area: Small Gas Engines

Problem: Principles of Engine Operation

Job: Multi-cylinder Engines

Motivation: Why does an 8 cylinder run smoother than a 4 cylinder? Then why not have all 12 cylinder engines?

Study Questions:

1. Why is it better to have several small cylinders instead of one large one.

2. Explain what is happening at a given instant in each of four cylinders. Use a drawing.

3. What would happen if the No. 1 and No. 4 plug wires were switched?

4. What are some of the differences in the total systems of a single cylinder engine and a 6 cylinder engine?

5. What determines the firing order?

6. What cylinder arrangements may be made on multi-cylinder engines.

7. Why not have a lawn mower engine with 4 small pistons?

Summary of Information:

1. There is less interval between firing causing smoother operation.

2.

Figure 4

13844

3. When either cylinder plug sparked the intake valve would not be open but would open at the wrong time.

4. Single cylinders, are usually air cooled and have no distributor.

5. The position of the lobes on the camshaft.

6.

Vertical

Horizontal
(example John Deere 2 cyl.)

Opposed
(Corviar, Volkswagon)

V-type
(V-8 engines)

Figure 5

7. There would be too many parts to complicate it. This would not be necessary with this low power requirement.

Ref. Purvis, pages 11, 30-34.

Teaching Suggestions: Use a chart showing what is happening in each cylinder at a given time. A movable model would be quite helpful.

138451

Problem Area: Small Gas Engines

Problem: Principle of Engine Operation

Job: Engine Timing and Condition

Motivation: How do valves happen to open at the correct time during the cycle? What does an oversized camshaft do to "soup up" a hot rod engine?

Study Questions:

1. How does the camshaft cause the valves to open?
2. How often does each valve open during the complete cycle?
3. How is the camshaft run at the proper speed so the valves open at the right time?
4. How does the engine get lubricated?
5. Why does an engine burn oil?

Summary of Information:

1. There are off center lobes in contact with the valve stems. Use a mock-up or model to show this.
2. Once each cycle.
3. A gear ratio of 2 to 1.
4. Oil is concentrated in the crankcase.
5. The rings are not fitting tight enough in the cylinder. This is usually the main cause.

Ref. Purvis, pages 51-53; Briggs and Stratton General Theories, pages 7-10.

Teaching Suggestions: Have students learn parts of the engine and illustrate the above questions on the disassembly job page 20.

138[illegible]1

Problem Area: Small Gas Engines

Problem: Measurements

Job: Use of Micrometer

Motivation: How can you measure the thickness of a fingernail (.002) or the diameter of a ball bearing or even the thickness of a tin can or a sheet of glass?

Study Questions:

1. What is a micrometer?

2. What is a micrometer used for in small gas engines?

3. How do you read a micrometer?

Summary of Information:

1. Micrometer: A measuring instrument for either external or internal measurement in thousandths and sometimes ten thousandths of an inch.

2. It is used to measure engine parts which have a very small tolerance.

   "Miking" should be done very carefully and accurately.

3. A. Scale on thimble reads from 0 to .025.

   B. Scale on sleeve reads from 0 to 10 (0" - 1.0").

      1. From 0 to 1 equals 1/10th inch; 0 to 2 equals 2/10ths inch; 0 to 5 equals 5/10th inch; etc.

      2. From 0 to 1 is subdivided into 4 parts (1/25th inch).

   C. Adjust micrometer to read 0.1 inch.

      1. Sleeve scale reads 1.

      2. Thimble scale reads 0.

   D. Now as you turn the thimble, the measurement reads 0.11; 0.12; 0.13; etc.

   E. Notice that on .125, the thimble now reads and the sleeve now is on the first subdivision (1/125th).

   F. Now turn thimble 1 revolution: Now reads .0150.

   G. Now turn thimble 1 revolution: Now reads .0175.

13847

H. Now turn thimble 1 revolution: Now reads .0200.

Ref. Shopwork On The Farm, M. M. Jones, page 411.
How To Run A Lathe, South Bend Lathe Company, page 39.

Teaching Suggestions: Demonstrate the use of a micrometer. Have students practice use of micrometer. Make transparencies of the following material for use in practice readings.

138

Problem Area: Small Gas Engines

Problem: What Needs To Be Repaired

Job: Disassembly and Checking the Engine

Motivation: How should a small engine be disassembled? What parts should be checked for wear?

Demonstration: Follow the disassembly procedure in Briggs and Stratton Repair Instruction II. Show Briggs and Stratton slides on disassembly.

Steps in disassembly and checking.

1. Drain oil.
2. Remove air cleaner and stud and any other parts of the engine that are made of plastic.
3. Drain fuel tank.
4. Remove blower housing.
5. Clean the engine with steam or solvent (cover the coil as solvent or steam might damage it).
6. Disassemble and check starter mechanism.
7. Spin flywheel to check compression.
8. Check spark.
9. Check air gap.
10. Check governor blade for wear.
11. Remove valve cover and check valve clearance.
12. Remove cylinder head bolts, indicate where long bolts belong, demonstrate threading and removal of stud that has been twisted off.
13. Remove valves and springs (point out different kinds of valve keeper and how they are removed).
14. Inspect valves and seats.
15. Check valve guides.

07864
13849

16. Remove starter pulley or starter clutch.

17. Remove flywheel. Demonstrate how to remove with Briggs and Stratton puller and removing the flywheel by striking the crankshaft sharply with a plastic mallet, while lifting on the flywheel.

18. Check flywheel key.

19. Remove breaker point cover (indicate the use of a sealer where the coil wire enters).

20. Check breaker point gap.

21. Remove condenser and points.

22. Check breaker point plunger and plunger hole.

23. Test condenser.

24. Test coil.

25. Check crankshaft end play.

26. Remove burrs from crankshaft extension and use emery paper to remove all rust so that bearing will not be distorted.

27. Remove base or sump.

28. Remove oil slinger.

29. Remove and check cam gear (emphasize timing marks, if they cannot be found use a punch to make the timing marks).

30. Remove and check tappets.

31. Ream ridge from top of cylinder.

32. Remove and check piston and rod.

33. Remove and check crankshaft.

34. Check cylinder bore.

35. Check main bearings.

36. Check condition of all threads and bolts. Remove any studs that have been twisted off and thread or use insert thread to restore original condition.

Ref. Briggs and Stratton Repair Instruction II

13850

Teaching Suggestions: All of the repair procedures should be demonstrated when each of the areas are studied.

Problem Area: Small Gas Engines

Problem: Ignition System

Job: Function and Parts

Motivation: What takes the place of the battery system in supplying the electrical spark for a small gas engine?

Study Questions:

1. What is the purpose of the ignition system?
2. What are the two types used?
3. Which of these is most common on small engines?
4. What is the principle difference between the two?
5. What are the advantages of the magneto system?
6. What are the parts of the magneto?
7. How do these parts function to provide a hot spark?
8. When should the spark occur?
9. What is the importance of a condenser?

Summary of Information:

1. Purpose - to ignite the air-fuel charge by means of a high voltage spark.
2. Types - magneto and battery.
3. Most common - magneto type.
4. Differences - principal difference is source of electrical current. In the magneto, the armature must be rotated to produce the necessary current. In the battery system, current is produced by chemical action.
5. Advantages - A. Does not require a battery for starting.
   B. Intensity of voltage increases with engine speed.
   C. Longer life span.

13851

6. Parts: A. Primary circuit:

1. Rotor with magnets - may be located in flywheel or in a rotor mounted on a crankshaft.

2. Laminated shoe plates or armature.

3. Laminated core inside of coil.

4. Primary windings, larger wires with few windings. (about 35 feet of wire)

5. Breaker points to open mechanically on a cam to open the primary circuit.

6. Condenser to store electricity when points are open.

7. Switch used to ground circuit to stop engine.

B. Secondary circuit:

1. Secondary winding, small wires with many windings, used to increase voltage. (about 3520 feet of wire)

2. High tension lead to spark plug.

3. Spark plug which ignites fuel in cylinder.

7. How parts function:

A. Rotor with magnets turn with crankshaft.

B. Flow of current changes direction every half revolution of rotor and is greatest just before a reversal of the magnetic flux.

C. Points are opened to cause an interruption in the flow of current in the primary winding.

D. Connected across the points is a condenser to absorb the surging current when the points are opened: preventing arcing and burning of the points.

E. Condenser storage action is followed by a quick and complete collapse of the magnetic field in the coil.

F. Collapse of primary current induces a secondary current.

13852

G. A much higher voltage is developed, since there are many more turns in the wire of secondary circuit.

H. High voltage enters the center of distributor cap which directs a hot spark to each plug just as the mixture has been compressed for burning.

I. In a 2-cycle engine, this sequence of events occurs 6000 times a minute. In a 4-cycle, it occurs 3000 times per minute at full RPM.

8. Spark occurs:

A. When starting: near HDC on compression stroke.*

B. For full speed: 25° - 30° BHDC on compression stroke.**

C. Proper engine timing means valves, magneto, and breaker points must be in proper relation to crankshaft rotation. (1/50th of a second off and engine might not run.)

9. Condenser:

A. It is a safety valve for primary circuit. If it shorts out, the points will burn and spark will be weak.

B. Current stored in condenser is used to re-energize the primary circuit when points are closed.

Ref. Purvis, pages 182-204; Briggs and Stratton General Theories, pages 19-24.

Teaching Suggestions: Have various parts of the ignition system available for student inspection. Use charts. Use actual engine to demonstrate on.

* HDC is an abbreviation for "head dead center". Sometimes referred to as TDC or "top dead center".

** BHDC means "bottom head dead center". Sometimes referred to as BDC or CDC which is "bottom dead center" or "crank dead center".

21 OF 327

ED

056 238

MICROCOPY RESOLUTION TEST CHART

NATIONAL BUREAU OF STANDARDS-1963-A

Problem Area: Small Gas Engines

Problem: Ignitions

Job: Magneto Care and Ignition Adjustment

Motivation: In a two cycle engine, spark occurs 6000 times per minute at this speed everything must function perfect.

Study Questions:

1. How can you check magneto output?
2. What type lubricant is used?
3. What points should be lubricated?
4. At what intervals should points be regapped?
5. What other adjustments can be made on the ignition system?

Summary of Information:

1. Output - gap a spark plug at 3/16" (.187) and connect the lead. Hold the plug against the head or block and crank the engine. If fire jumps readily across the 3/16" gap, the output is adequate. Or a spark tester can be used.

2. Lubricant - a light grade engine oil or highly refined lubrication oil should be used, but used sparingly.

3. Lubrication points - A. A few drops of oil should be applied to armature, or rotor bearings and to distributor bearings.

   B. If impulse is sluggish, flush with kerosene and reoil with light grade oil.

4. Regapping - points usually needed regapping or replaced after 200 to 300 hours of operation.

5. Adjustments -

   A. Spark plugs:

      1. Clean and file electrodes.

      2. Set proper gap. Use wire gauge.

      3. Replace if necessary.

13823

12854

B. Breaker point gap:

1. File lightly.

2. Replace if pitted.

3. Use flat feeler gauge and set according to specifications.

C. Air gap:

1. Use feeler gauge and set according to specifications. Or paper tags can be used.

D. Breaker point plunger hole:

1. If loose, it will leak oil on points.

E. Check condenser.

Ref. Purvis, pages 193-205; Briggs and Stratton General Theories, pages 19-24.

Teaching Suggestions: Demonstrate the various ignition repair procedures, see demonstrations next five pages.

13855
13826

SERVICING THE IGNITION SYSTEM*

Breaker points

Remove the breaker point cover and examine the condition of the points. If they are burned or pitted, they should be replaced. If you replace the points, have the condenser tested or replace it too.

Adjust the clearance between the breaker points when fully open to that recommended. For our example engine this clearance is .020. Wipe the blade of your feeler gauge clean of oil or grease before you use it to check point setting.

Spark plug

Inspect the spark plug for fouling, wide gap, or burned condition. Cleaning a dirty plug is a questionable practice. If in doubt, it is best to replace it with a new plug of the proper number as specified by the engine manufacturer.

Adjust the plug gap to the recommended clearance. For the example engine this is .025.

Coil and ignition wiring

The coil and ignition circuit can be tested with a 6-volt lantern battery as shown in Fig. 6. It is convenient to have a clip on the end of one battery wire and a test prod on the end of the other.

Figure 6. A coil and ignition circuit tester.

Figure 7. Clip one battery wire to the engine frame. Scratch the insulated breaker point with the prod and a spark should jump the plug gap.

13856

Connect the spark plug wire to the plug and lay the base of the plug in contact with the engine head. Clip one battery wire to the engine frame. Turn the engine until the points are fully open and scratch the insulated part of the breaker point assembly with the test prod (Fig. 7). A spark should jump the gap at the plug. The spark is most intense when you touch the prod to the insulated point for a moment and then break contact quickly. This simulates the action of the breaker points when the engine is running.

If you get no spark at the plug, do not conclude immediately that the coil is defective. The trouble may be in the points, in the primary wire leading from the points to the coil, in the coil grounding wire, or in the secondary wire leading from the coil to the plug.

Note what kind of a spark, if any, occurs when you scratch the insulated point with the battery prod.

No spark. This means that the current is not going through the primary ignition circuit. Look for a poor connection or a break in the wire leading from the point assembly to the coil. A loose connection at the point where the coil winding is grounded will also cause this fault (Fig. 8).

Figure 8. The armature ground wire must be tight.

Figure 9. The spark plug wire should be pinched tight but not soldered.

Small spark. A small spark of the same intensity that you get when you scratch the prod on the engine frame indicates that the insulated breaker point assembly is grounded somewhere. This may be due to the lug on the wire attached to the insulated point touching the frame, or to a break in the insulation on the wire leading from the point to the coil. Do not overlook the shorting mechanism that may be used to stop the engine. If your engine has a switch to turn it off, or if you close the throttle to stop it, this mechanism may be shorting out the points continuously.

13857 13828

Bright spark. This indicates that the primary circuit of the coil is probably all right. When you energize the primary circuit, a magnetic field builds up in the coil. When you break this circuit, the primary field collapses, giving a momentary surge of fairly high voltage back through the primary circuit. This causes a bright blue spark at your prod.

If you still get no spark at the plug and you are sure the plug base is making good contact with the engine head, look for trouble in the secondary circuit. Check the connection of the spark plug wire to the coil. It should be pinched tight as shown in Fig. 9 but not soldered.

Look next for worn insulation on the spark plug wire, particularly where it passes through openings in the frame or under metal clips. High-voltage current may be shorting to the frame at these points. There may also be a break in the wire somewhere between the coil and the plug. To check these possibilities, disconnect the spark plug wire from the coil and connect a new piece of wire directly to the coil and plug.

If the plug still fails to fire, you may conclude that the coil is defective and should replace it with a new one.

*University of Illinois, Small Engine-Repairs and Over-haul

13858

Problem Area: Small Gas Engines

Problem: Ignition

Job: Replacing Breaker Point Plunger Bushing

Demonstration:

1. Check breaker point plunger for length, reject at less than .870 inch.

2. Check breaker point plunger hole with plug gauge 19055.

3. Use reamer 19056 to ream plunger hole (remove all ignition parts from block).

4. Drive in bushing with bushing driver 19057 so the upper end of bushing is flush with the boss.

5. Finish ream the bushing with reamer 19058.

6. Insert new plunger with groove to the top.

Ref. Briggs and Stratton Repair Instruction II, page 16.

13859

13860

Problem Area: Small Gas Engines

Problem: Ignition

Job: Installing and Adjusting Points and Condenser

Demonstration:

1. Install mounting post of breaker arm in recess so that groove in post fits into the notch in the recess and tighten.

2. Place spring on arm and place in the groove on the post.

3. Connect primary coil wire on condenser and install the condenser. If ground wire for stopping the motor is present attach it to the condenser also.

4. Turn crankshaft until points are open as far as they will go.

5. Loosen the condenser and insert a .020 flat feeler gauge between the points. Move condenser to correct setting with a screw driver and tighten condenser bracket.

6. Always check to see that there is no grease or other foreign material on the points and that the points are meeting squarely.

7. Place a little sealer on the slot through which the coil wires pass on the breaker point cover so that dirt will not enter.

Ref. Briggs and Stratton Repair Instruction II, page 16.

13829

13860

Problem Area: Small Gas Engines

Problem: Ignition

Job: Setting Armature Air Gap

Demonstration:

1. Place coil on engine and tighten one screw to hold it in the highest position

2. Place proper thickness gauge between armature and flywheel. Refer to Briggs and Stratton Repair Instruction II, page 18.

3. Point out differences between aluminum and zinc flywheels.

4. Loosen the one mounting screw, the magnets should pull the coil down firmly against the thickness gauge.

5. Tighten the mounting screws.

6. Rotate flywheel to remove thickness gauge.

Ref. Briggs and Stratton Repair Instruction II, page 18.

13861

Problem Area: Small Gas Engines

Problem: Ignition

Job: Spark Plug

Motivation: New plugs may reduce fuel consumption 14.2% or from 10 gallons per hour to 8.6 gallons per hour. This results in a savings of approximately 32¢ per hour.

Study Questions:

1. What is the function of the spark plug?
2. What are the three types of spark plugs?
3. Does a "hot" plug deliver a hotter spark than a "cold" plug?
4. What is the difference in the three plugs?
5. How do you determine the heat type needed?
6. What is the danger of plugs overheating?
7. What type gauge should be used to gap plugs?
8. What is meant by spark plug "reach"?
9. What are the common lengths of "reach"?
10. What torque should be used for spark plugs?

Summary of Information:

1. Function - to transfer a high voltage spark from the lead wire to the combustion chamber.
2. Different plugs - "hot" - "normal" - "cold".
3. Hotness of spark - the voltage of the spark is the same in any of the three plugs.
4. Differences - the difference in the three plugs is the length of insulator tip. The length determines how rapidly heat passes from the spark plug to the engine cooling system.
5. Heat type -

   A. Hot plugs have a long insulator nose, therefore, heat must travel farther to reach coolant. This type is used for low-quality fuels or at low operating speeds.

   B. Normal plugs are used for average conditions.

13861

13862

C. Cold plugs have a short insulator nose, and operate at a lower temperature. They are used on high-quality fuels or at high operating speeds.

6. Overheating - this may cause blistering, burning of electrodes and engines knock. Engine knock is caused by hot plugs that ignite the fuel charge before the spark plug fires. This is at a temperature of 1600° - 1700°.

7. Plug gap - should be set with a wire gauge to insure proper gapping of convex or concave areas.

8. "Reach" refers to the distance from the top of the copper gasket to the bottom of the ground electrode.

9. In the 14 mm plug, there are four different lengths, of "reach"; 3/8, 7/16, 1/2, 3/4. These are designed to fit different types of engine heads so the base of the plug will be even with the inside of the combustion chamber.

10. Torque - cast iron heads - 30 foot lbs.
aluminum heads - 25-27 foot lbs.

Ref. Purvis, pages 205-209.

Teaching Suggestions: Have plugs of the various types available for observation. Follow this lesson with a few days in laboratory with students working on the ignition systems of small engines.

RATCHET RELEASE

1383

Problem Area: Small Gas Engines

Problem: Ignition

Job: Checking, Cleaning and Setting Spark Plugs

Demonstration:

1. Remove dirt from around spark plug seat.

2. Remove spark plug from the engine (emphasize proper procedure and tools to keep from breaking plugs).

3. Clean the plug.

4. Show correct procedure for setting and gapping a spark plug. Illustrate why a wire gauge is better than a flat feeler gauge for gapping spark plugs.

5. Clean plug in solvent to remove any sand left from the cleaning procedure.

6. Replace plug in engine and tighten until spacer washer is depressed. Emphasize right amount of torque in tightening so as not to strip the threads in aluminum heads.

13863

13864

Problem Area: Small Gas Engines

Problem: Carburetion

Job: Principles of Carburetion

Motivation: Why not just put gasoline directly into the cylinder? Why have a 4 barrel carburetor instead of one large one?

Study Questions:

1. What is the basic purpose of the carburetor?
2. What is a venturi?
3. What is an airfoil?
4. In what ways may gasoline get into the carburetor?
5. What does the carburetor float do?
6. Explain how the fuel goes from the carburetor into the cylinder?
7. What is the ideal combustion mixture of air and gasoline?

Summary of Information:

1. To vaporize the gasoline and mix it with air.
2. A narrow area through which air must flow. It causes an increase in speed and a decrease in pressure of the air.
3. A tube in a stream of air inside the venturi which creates an air pattern with low pressure on one side.
4. Gravity feed, fuel pump, suction of the carburetor.
5. Regulates the amount of fuel in the bowl of the carburetor.
6. As the engine is turned over, the intake stroke creates a suction in the manifold and through the carburetor. Air rushes in through the venturi. Gasoline is already in the nozzle located in the venturi. As the low air pressure is produced on the backside by the airfoil the fuel comes out through little holes and is mixed with the air rushing into the manifold.
7. 14 to 15 lbs. of air to 1 pound of gasoline.

Ref. Purvis, pages 137-151; Briggs and Stratton General Theories, pages 10-19.

Teaching Suggestions: Use Briggs and Stratton, General Theories of Operation, as an additional reference on carburetion.

138658

Problem Area: Small Gas Engines

Problem: Carburetion

Job: Types of Carburetors

Motivation: We know there must be differences in carburetors since we hear about 2 barrel and 4 barrel carburetors. How much difference is there other than this? Show several different carburetors.

Study Questions:

1. What parts are about the same in all types?

2. What parts differ among them?

3. What problem of carburetion is taken care of with modern types of carburetors, but was overlooked in early carburetion systems.

4. What methods are used to overcome this problem and how does each work?

5. What is the difference between updraft, downdraft, and side carburetors?

Summary of Information:

1. Float system, throttle and choke systems, and the relationship of parts to obtain fuel air mixture.

2. Number of jets and position of jets. Angle to manifold may vary.

3. When the engine is idling, it needs a richer mixture than when operating at medium speeds. At maximum power, a rich mixture is again needed.

4. A. Idling Jet. The idling jet is necessary at low speeds because the vacuum is too low to bring fuel through the regular jet. It discharges fuel into the mixing tube close to the throttle in the closed position. The vacuum is high at that point when the throttle is closed. As soon as the throttle is opened, the vacuum shifts from above the throttle to below it and receives fuel from the main jet instead of the idle jet.

   B. Double nozzle. (D-8, p. 142) Purvis.

   In addition to the main nozzle, there is another nozzle with a constant rate of discharge. The compensating nozzle receives its supply from a standpipe connected to the float chamber and open to the atmosphere so that it delivers at a constant rate.

138661

C. Air Bleed Principle (D-9, p. 144) Purvis.

Consists of a secondary venturi, a well jet, and a discharge jet in addition to a regular carburetor. Air going through the discharge jet at low speeds decreases surface tension and allows more fuel to flow in at low vacuum. A small amount of air enters through the well vent. A ring discharge in the secondary venturi takes care of fuel at high speeds.

5. A. Updraft - connects below the manifold.

B. Downdraft - connects on top of the manifold. (This way in car engines.)

C. Side - comes into the side of the manifold, and has a horizontal air passage.

Ref. Purvis, pages 137-151, Briggs and Stratton General Theories, pages 10-19.

Teaching Suggestions: Use cutaways or old carburetors to show types. Use charts showing internal structure of carburetors.

13867

Problem Area: Small Gas Engines

Problem: Carburetion

Job: Adjusting the Carburetor

Motivation: Could you adjust a carburetor for top efficiency? Is top efficiency the same as top performance?

Study Questions:

1. How do you adjust a carburetor to have maximum power?

2. What do we mean by a lean mixture? What's wrong with a lean mixture?

3. How does the throttle work?

4. How is the idle mixture adjusted?

5. How does the choke accomplish its purpose?

Summary of Information:

1. Run the engine at operation speed. Turn the needle valve until the engine slows down. Then turn the needle valve out until the engine speeds up then slows down. Turn the valve back to a point half-way between these two points.

2. A small amount of gasoline compared to the air in the mixture. Not economical, causes overheating, detonation, and short valve life.

3. A butterfly is located above the venturi which regulates the fuel mixture going into the cylinder.

4. Set the engine at idle (about 1750 RPM) turn the valve down until it slows, then back it up until it speeds up then slows down. Turn it back to half-way between.

5. The choke is a butterfly placed below the venturi. It regulates the flow of incoming air. When it is closed the ratio of air to fuel is low or the mixture is rich.

Ref. Purvis, page 146, Briggs and Stratton General Theories, pages 10-19.

Teaching Suggestions: Demonstrate adjusting 2 or 3 kinds of carburetors. Try the engine at different adjustments to show the effects on engine operation.

13868

Problem Area: Small Gas Engines

Problem: Carburetion

Job: Rebuilding Carburetors

Motivation: Faulty carburetors are the leading cause of small engine failures. How can a carburetor be repaired?

Study Questions:

1. Why is it necessary to replace carburetor gaskets?

2. How do you check for upper carburetor warpage?

3. When will needle valves, idle valves and float valves need to be replaced?

4. How can you check throttle shaft wear?

5. How can the float adjustment be made?

Summary of Information:

1. Gaskets may harden or crack and cause leakage.

2. Insert .002 feeler gauge between upper and lower body. If feeler gauge will go the upper body will need to be replaced.

Figure 10 Checking Carburetor Body Warpage
Courtesy Briggs and Stratton

3. When any of the needle valves have ridges worn or have seats damaged they will usually both need replacing.

4. Replace bushing if throttle shaft has .010 or more play. Place and iron bar under throttle shaft, use a feeler gauge and lift shaft. If .010 or more play is found it will need bushing.

13869

Figure 11 Checking Throttle Shaft Wear
Courtesy Briggs and Stratton

5. Adjustment is made by bending tang. It should be the same distance from each side of the float to the carburetor body.

Ref. Briggs and Stratton Repair Instructions II page 23-40.

13870

Problem Area: Small Gas Engines

Problem: Carburetion

Job: Rebuilding Carburetors

Demonstration:

1. Demonstrate the disassembly of a carburetor.

   a. Stress how easily carburetor parts can be lost or misplaced.

   b. Indicate the correct use of tools.

   c. Show students how jets can be removed without damaging carburetor body.

2. Demonstrate how parts are to be prepared to put into carburetor cleaner. Emphasize the caustic actions of the cleaning material.

3. Replace throttle shaft bushing.

4. Demonstrate correct assembly procedures.

Ref. Briggs and Stratton Repair Instruction II, page 25.

Teaching Suggestions: Show slide on carburetor overhaul by Briggs and Stratton.

13871

Problem Area: Small Gas Engines

Problem: Carburetion

Job: Fuels

Motivation: Why do we have several grades of gasoline?

Study Questions:

1. What kind of gasoline is recommended for small 4 cycle engines?
2. What is meant by a volatile fuel?
3. What is vapor lock: What causes it? How can it be prevented or corrected?
4. How should an engine which will not be used for a month or more be stored?
5. What function does the air cleaner have? How important is this?
6. How does the fuel for a two cycle engine differ from that for a 4 cycle? Why is this?

Summary of Information:

1. Regular grade. Use winter grade in winter and summer grade in summer.
2. One which evaporates at a low temperature.
3. The fuel vaporizes before it goes into the venturi. Low air pressure, high temperatures or too volatile a fuel. Use proper fuel, don't allow the engine to run too hot because of overload or poor adjustment. Put heat dissipating fins on the fuel line.
4. The fuel should be drained from the tank and the carburetor.
5. It traps dust and grit from the air so the air going into the carburetor is clean. Grit in the cylinder can wear it out very quick. There is about 390 cubic feet of air per hour at 24 miles per hour entering the engine.
6. It contains an oil mixed with the gasoline. This is the only means of lubrication since the fuel goes into the crankcase before going into the combustion chamber.

Ref. Purvis, pages 137-151; Briggs and Stratton General Theories, pages 10-19.

Teaching Suggestions: Prepare an engine for storage. Take a dirty air cleaner off and show what it has taken out of the air. Mix some fuel for a 2-cycle engine.

13872

Problem Area: Small Gas Engines

Problem: Valves

Job: Principles

Motivation: Valves in the internal combustion engine are possibly a greater problem than any other part of the engine. They are exposed to extremely high temperature and open 2000 times per minute when the engine is running 4000 RPM.

Study Questions:

1. What is the purpose of the valve?
2. What are the various types of valves?
3. What are the parts of the valve train?
4. What are the two valves found in the engine?
5. What is the greatest problem concerning valves?
6. How is this heat dissipated?
7. What is the operating temperature of the valve face?
8. Why does the temperature differ from the valve and the cylinder?
9. Does air become cooler or warmer with movement?
10. What are some methods of cooling valves that are not used?
11. Why aren't the items in number 10 above used?

Summary of Information:

1. To permit a fuel charge to enter and escape from the combustion chamber.
2. A. Poppet

   B. Rotary

   C. Sleeve

13873 13874

10.

IDLER PULLEY

11.

GEAR CASE

1384 [redacted]

3.

4. A. Intake

   B. Exhaust

5. Many may reach 5000° which is beyond the melting point of iron. Exhaust valves often operate at a red heat.

6. How is this heat dissipated?

   A. Top of intake is cooled by incoming air.

   B. Contact between valve and cylinder and block.

   C. Heat flows from valve head to valve seat. (slight)

   D. Valve stem is hollow and filled with metallic sodium.

   E. Heat is transferred from valve stem to tappet and camshaft assembly.

13874

7. About 1000° to 1200° with the center reaching 1400°.

8. Heat will flow through a solid piece of metal more efficiently than from one piece to another.

9. Temperature of air rises in direct proportion as speed is increased.

10. A. Larger openings in order to slow air speed.

    B. Surface contact between valve stem and block.

    C. Increase weight of valve.

11. A. Limited space in combustion area.

    B. Valves often need replacement and guides may need to be replaced.

    C. Valve speed requires as light a weight as possible

Ref. Purvis, pages 80-95; Briggs and Stratton General Theories, pages 7-10. Briggs and Stratton - Wall Charts.

Teaching Suggestions: Use a large chart showing parts of the valve. Use a cutaway or partly torn down engine. Show some valves and valve seats that are defective in some way.

13875

Problem Area: Small Gas Engines

Problem: Valves

Job: Valves for 2-cycle Engines

Motivation: Do 2-cycle engines have valves? What actually is a valve?

Study Questions:

1. How does the 2-cycle engine differ from the 4-cycle engine?
2. How is the air taken into the cylinder?
3. List the action of the intake leaf valve.
4. How does the exhaust open and close?

Summary of Information:

1. Instead of true valves, the 2-cycle engine uses a check valve system.
2. A. Piston creates a vacuum which draws a charge of air in at atmospheric pressure.

   B. Special blowers, or superchargers are used on the large 2-cycle engines (GM diesel).
3. A. The leaf is open when the piston is compressing the charge in the cylinder.

   B. The leaf is open when plug fires.

   C. The leaf is closed on the power stroke.

   D. The leaf is closed when exhausting burned gases.
4. The piston covers the port to seal any leakage. In the 2-cycle, the piston does all of the work of the valve.

Ref. Purvis, pages 14-15.

Teaching Suggestions: Show students a check valve in a 2-cycle engine. Use chart or mock-up or a 2-cycle engine to explain valve action.

13876

Problem Area: Small Gas Engines

Problem: Valves

Job: Valve Distortion

Motivation: You can imagine the results if a valve is bent. With the valve moving so rapidly, heat can easily build up and cause distortion. How can we prevent this?

Study Questions:

1. What is valve distortion?
2. What is the primary factor causing face and seat distortion?
3. How is the seat affected?
4. How does distortion affect the clearance of the valve?
5. Why is aluminum used for heads and blocks?
6. Why aren't valves made from aluminum?

Summary of Information:

1. A hot spot which causes unequal expansion of the valve which caused improper seating or uneven wear.
2. The rim (margin) is too thin or uneven. A margin of 1/32" is considered minimum.
3. When the valve and seat are cold, they may mate properly but when hot, the valve may "climb off of the seat". B-61, P.84, Purvis.
4. Due to expansion of the stem, the valve may tend to leak when at operating temperatures.
5. Aluminum is a rapid conductor of heat which offers heat dissipation more readily.
6. The melting point of aluminum is low, about 1200°F.
   Note: Demonstrate the heat conductivity of various metals, the rate of expansion and the melting points. Show a cutaway valve and the principles of the valve action in the cutaway engine.

Ref. Purvis, pages 80-86.

Teaching Suggestions: Show a valve and seat that has worn unevenly. Show a proper fitting valve in seat.

13877 13876

Problem Area: Small Gas Engines

Problem: Valves

Job: Lapping and Springs

Motivation: How many have ever done or helped do a valve job on any engine?

Study Questions:

1. What is hand lapping of valves?
2. Why was this method unacceptable?
3. What is concentricity of valve with the seat?
4. Why is the valve spring important?
5. What should be checked on the springs?
6. Why should the above be checked?

Summary of Information:

1. Placing a grinding compound, which was usually an abrasive paste (emery powder and vaseline) on the surface of the valve and oscillating the valve until the valve and seat are mated.

2. Little attention was given to valve seat width, heat dissipation, concentricity of valve with seat, strength of valve spring or wear in the guides.

3. Concentric -- that which has a common center with something else. The valve must have a common center with the seat.

4. The valves are opened by the cam lobe with lightning-like speed and the spring is expected to close just as fast. (1/50th of a second).

5. A. Squareness

   B. Free and compressed length

   C. Pounds of compression

   D. Etching

6. A. If the spring isn't square, it will tend to pull the stem to one side and cause undue wear on the stem and guide.

   B. If spring is too short, it will not properly close the valve.

13878

Problem Area: Small Gas Engines

Problem: Valves

Job: Grinding Valves and Seats

Motivation: How many know how to adjust valves? What is the purpose of grinding valves?

Study Questions:

1. What is the usual tolerance for valve stems?
2. At what angle should the valve seat be ground?
3. At what angle should the valve face be ground?
4. What are the steps in replacing the seat?
5. What tolerance should be maintained between valve and tappet?
6. What adjustments can be made as to valve tolerance?
7. What is the purpose of the camshaft?
8. What are the parts of the camshaft?
9. How is the lobe designed?

Summary of Information:

1. .002-inch with a margin of 1/32-inch.
2. 45 degrees*.
3. 45 degrees*.

Valve Dimension

Figure 12
Courtesy of Briggs and Stratton

13820881

4. A. If screw in type, unscrew old seat.

   B. Pull or break out old seat.

   C. Block should be cleaned and free from carbon.

   D. Freeze new seat and fit into position.

   E. Check for proper fit. Maybe it will be necessary to oversize seat.

   F. Peen to secure position.

5. .014 - .016"*.

6. A. Often an adjusting tap is located on the tappet.

   B. If model does not have tap, valve stem must be ground or filed to tolerance. Care should be taken not to remove too much of the stem.

7. To control the action of the valves.

8. Nose, ramp, heel.

9. To open the valves smoothly. The valve is forced open gradually as the tappet starts up the ramp. The valve is in a full open position when tappet is on the nose.

Ref. Purvis pages 80-95.

Teaching Suggestions: Demonstrate adjusting tappet clearance. See demonstration lesson plan on next page. Use engine cutaway to show how camshaft and valves operate.

*The operators manual should be used as engines differ in specifications.

200 OF 327

ED

056 238

MICROCOPY RESOLUTION TEST CHART

NATIONAL BUREAU OF STANDARDS-1963-A

Problem Area: Small Gas Engines

Problem: Valves

Job: Replacing Valve Guides

Demonstration:

1. Check valve guides with gauge 19122. If flat end goes in more than 5/16 of an inch then bushing is necessary.

2. Use reamer 19064 in drill press, drill only 1/16 inch deeper than the length of the new bushing.

3. Clean all metal cuttings from valve guides.

4. Use bushing driver 19065 to press bushing in until top is flush with valve guide.

5. Finish ream the bushing with reamer 19066.

Ref. Briggs and Stratton Repair Instruction II, page 9.

UNIT VII - WORKING DRAWINGS

One- and Two-View Drawings Lesson 4

OBJECTIVE: To learn when and how to use one- and two-view drawings.

FIG. 1

RELATED INFORMATION:

An object is always drawn with the least number of views that will describe its form and size. Sometimes the number of views can be reduced from three to two, by dropping either the top or side view (Fig. 1). This is done when all features can be read either from the front and side views, or from the front and top views.

For two-view drawings, select views which show the most information and the fewest hidden lines. A front view usually presents most features of the object.

FIG. 2

1385

Problem Area: Small Gas Engines

Problem: Valves

Job: Grinding Valves

Tools and Supplies Needed: Valve spring compressor, screw driver, needle nose pliers, lapping tool, lapping compound, valve grinding machine.

Demonstration:

1. Remove valve spring cover.
2. Set valve spring compressor and compress valve spring.
3. Use pliers to remove pin, or retainer.
4. Pull valve from guide. It is very important that valves be handled so that they are not dropped as they can be easily damaged.
5. Remove valve spring and retainers.
6. Use a wire brush and carbon scraper to remove all carbon from the valve.
7. Check valve for excess wear. If margin is less than 1/64 inch discard.
8. Grind valve face to 45 degrees. Check valve on light cut to determine any warpage or bent valve stem. Check again to see if margin is over 1/64 inch.
9. Clean valve thoroughly with a solvent cleaner to remove any grit.
10. Proceed to problem on cutting valve seats.

Ref. Briggs and Stratton Repair Instruction II, page 8.

Teaching Suggestions: See illustration on page 61.

13883

Problem Area: Small Gas Engines

Problem: Valves

Job: Cutting Valve Seats

Motivation: Why should one cut the valve seats after bushing the valve guides?

Demonstration:

1. Check to be sure that seat is free of carbon and is secured in the block.

2. Insert proper pilot into valve guide.

3. Place cutter on pilot, use proper side (44 degree), see instruction manual.

4. Always check cutter to see that it is set for that particular seat and that the adjustments are tight.

5. Apply wrench and handle, turn 2-3 rounds applying a slight down pressure.

6. Remove cutter and check valve seat. Continue cutting until seat is cut all the way around.

7. Check seat for proper width (3/64 inch to 1/16 inch) if it is to wide turn the cutter over using the 30 degree side to narrow. Cut a slight amount and check width. Care should be taken not to over cut.

8. Take the previously ground valve, apply a small amount of lapping compound and place valve in seat. Then with the lapping tool, lap valve until you are sure valve is making contact all the way around.

9. Use a solvent and clean valve, seat and guide thoroughly.

Ref. Briggs and Stratton Repair Instructions II, page 8.

Teaching Suggestions: See Figure 13 and 14, page 57.

13883
13884

Problem Area: Small Gas Engines

Problem: Valves

Job: Replacing Valve Seats

Demonstration:

1. After cleaning valve seats check for cracks, eroded spots or loose seats. Should you find any of these a valve seat should be replaced.

2. If valve seat is bad use seat insert puller according to manual and remove seat.

3. Select the valve seat insert, correct pilot and drive according to manual.

4. Face seat in same manner as preceeding job "Cutting Valve Seats".

Ref. Briggs and Stratton Repair Instructions II, page 10.

13885

Figure 13
Courtesy Ethyl Corporation

Valve Seat Location

Usually after grinding valve seats the seat is too wide. This can be changed by using either a 30 degree stone or a 60 degree stone for a seat cut at 45 degrees. Narrowing the seat in this manner will many times change the inside or outside diameter of the seat. Thus the location of the seat with the valve face will be changed. To correct this the seat will need to be relocated.

VALVE REFACING

Figure 14
Courtesy Ethyl Corporation

Valve Margin

Valve margin should be checked after they have been ground. If the margin varies over .002 inch it is warped or has a bent stem.

New valves have been found to be damaged in shipment. It is therefore a good policy to grind a new valve.

13886 13885

INTERFERENCE ANGLE

Figure 15
Courtesy Ethyl Corporation

Interference Angle

Interference angles is the difference between the angle of the seat and the valve face. This angle is usually between 1/2 and 1 1/2 degrees. It is believed that this technique will provide a line contact between valve face and valve seat. Thus improving valve seating after repair and contributing to longer valve life.

13887

Problem Area: Small Gas Engines

Problem: Lubricating Systems and Lubricants

Motivation: How many have ever heard the statement, "the engine burned up"? Is there really any difference in different brands of oil?

Study Questions:

1. What is the purpose of lubricants?
2. What are lubricants made from?
3. What are the jobs a lubricant must perform?
4. What is meant by "viscosity"?
5. What does the SAE oil number mean?
6. Can the quality of the oil be judged by the SAE number?
7. What are the common weights that are used?
8. What does the "W" designate?
9. What does ML, MM, MS, DG, DM, and DS mean when stamped on the oil can?

Summary of Information:

1. To reduce internal friction in order to (1) obtain more usable horsepower and (2) to reduce operating temperatures.
2. They are made from the same crude oil from which we obtain gasoline. Often they contain animal fats, vegetable oils, and other ingredients such as silicones.
3. A. To reduce friction between moving parts.
   1. reduce heat that would be generated.
   2. conserve power.

   B. Act as a seal to prevent leakage.

   C. Carry away heat.

   D. Wash away abrasive metal.
4. The resistance to flow or adhesiveness characteristics of an oil.

13888

5. Various weights of oil are assigned a number by the society of automotive engineers. The lower the number the lighter the oil.

6. No. Only the weight.

7. Summer - 30 weight.

   Winter - 10 weight.

8. The "W" indicates that the oil has the ability to remain fluid at a lower temperature. IOW-30 means the oil is 30 weight yet will flow at the same temperature as 10 weight.

9. ML, MM and MS are designations for gasoline engine service.
   ML - light service, MM - moderate service, MS - severe service.
   DG, DM and DS are designations for diesel engine service.
   DG - general, DM - moderately severe, DS - very severe.

Ref. Purvis pp. 101-102; Standard Oil FT-53 Farm Tractors, pp. 66-80.

Teaching Suggestions: Use old oil cans and discuss labeling.

00813889

Problem Area: Small Gas Engines

Problem: Lubricating Systems and Lubricants

Job: Oil Selection

Motivation: How can there be any difference in oil? What is the difference in the origin of oil and grease? Show the difference in the way different oils pour.

Study Questions:

1. What factors are considered in recommending weights of oils?
2. What weight might be used in a new engine?
3. What weight might be used in an old engine?
4. What is a general rule that should be followed?
5. What are the advantages of a light oil?
6. What are the disadvantages of a light oil?
7. What are the three factors with which oil must contend?

Summary of Information:

1. A. Existing temperatures.
   B. Engine clearance.
2. A. Summer - 20 weight.
   B. Winter - 5-10 weight.
3. A. Summer - 30 weight.
   B. Winter - 20 weight.
4. Use the lightest weight that can be used safely.
5. A. Allows easier starting.
   B. Attains circulation faster.
6. It may not maintain a film of protection between moving parts.

C88013890

7. A. Heat; head often reaching 1000° to 1200°.

   B. Speed; up to 6000 - 7000 RPM's.

   C. Pressure; as the piston travels up, it pushes against the cylinder wall.

Ref. Purvis pp. 102-103, Standard Oil FT-53 Farm Tractors pp. 66-80.

Teaching Suggestions: Use chart relating to oil selection.

13891

13835

Problem Area: Small Gas Engines

Problem: Lubricating Systems and Lubricants

Job: Lubrication Methods

Motivation: Would it be possible to have all engine parts submerged in oil? If not how can oil get to all working parts?

Study Questions:

1. What are the two types of lubrication?
2. Which of these is most common on small engines?
3. How does the spash method work?
4. How is the upper cylinder lubricated in a 2-cycle engine?
5. How does the pump operate?
6. How many pounds of pressure does the pump operate?
7. What is the advantage of each system?

Summary of Information:

1. A. Splash.

   B. Pump.

2. The splash method is most common but both may be used.
3. By employment of a cup which is attached to the cap of the connecting rod. This dips into the oil with each revolution in order to lubricate the journal. Also this splashes oil over other moving parts. (Show splash cup)
4. Oil is mixed with the gasoline (1:16) and when injected into the combustion chamber, it will cling to the walls.
5. The pump supplies oil under pressure to all moving parts of the engine. This assures a continuous oil supply.
6. Depending on the size of the engine. Small engines operate at from 4-6# while truck engines may run at 45-60#.
7. A. Splash: fewer parts, less maintenance.

   B. Pump: assured lubrication; lubricates all parts regularly.

Ref. Purvis 103. Standard Oil FT-53 Farm Tractors pp. 66-80.

Teaching Suggestions: Use an oil pump for observation.

13892

Some objects, such as cylinders, have all cross sections of the same shape. These can be shown in one-view drawings.

As Fig. 2 indicates, one-view drawings differ from two-view drawings by omission of the end or side view and the substitution of a notation to indicate the cross-sectional shape. Single-view drawings are usually made for objects whose cross sections are rectangular, square, hexagonal, octagonal, or round.

QUESTIONS:

1. Name two cross-sectional forms that are adaptable to one-view drawings.

2. How does a one-view drawing differ from a two-view?

3. What advantages arise from using fewer views of an object?

4. Who makes the decision as to the number of views to be used?

5. In making a two-view drawing, which views should be selected?

Problem Area: Small Gas Engines

Problem: Lubricating Systems and Lubricants

Job: Accessories.

Motivation: Why is it important to make sure that the air is filtered before it enters the carburetor? What other parts or precautions are taken to make sure dirt does not enter the working parts of the engine? Show a dirty air filter. And bring the point, what would happen if all this dirt was in the cylinder and carburetor.

Study Questions:

1. List two of the accessories found on a 4-cycle engine.
2. Why is it necessary to have an air cleaner?
3. What are two types of air cleaners?
4. How often should the oil bath cleaner be serviced?
5. How should they be cleaned?
6. How does the oil-bath cleaner operate?
7. What is the function of the gasoline strainer?
8. How often should the strainer be checked?

Summary of Information:

1. A. Air cleaner.

   B. Gasoline strainer.

2. The engine burns 16-17 parts of air to 1 part of gasoline by weight. This means that 8000 gallons of air is burned to every gallon of gasoline.

3. A. Oil bath type.

   B. Dry type.

4. In dirty conditions, every day (10) hours.

5. By washing with gasoline. Breather caps should never be burned as this leaves carbon in the cap.

6. Air is drawn through the oil and then filtered.

13834

13893

7. To prevent sediment, dirt and water from entering the carburetor.

8. Every day (10 hours).

Ref. Purvis, page 149; Standard Oil FT-53 Farm Tractors, pages 32-55.

Teaching Suggestions: Demonstrate servicing an air cleaner of each type. Demonstrate servicing a gasoline filter. Demonstrate cleaning a breather cap. Use large diagram to illustrate air cleaner.

13894

13893

Problem Area: Small Gas Engines

Problem: Cooling System

Job: Principles of Air Cooled Engines

Motivation: What difference is there in the appearance of an air cooled and a water cooled engine? What difference does this make in the way you would want to operate them?

Study Questions:

1. At what temperature should an engine be used?
2. What percentage of the heat energy is used?
3. How is the heat dissipated in an air cooled engine?
4. Why is aluminum used in air-cooled engines?
5. What is the function of the fins on the head?
6. Why should the head be kept clean?
7. What precaution should be used on water cooled engines?
8. Why will lime deposits retard cooling?
9. What occurs when lime or rust accumulates in the engine?
10. What is the danger of adding water to a hot engine?

Summary of Information:

1. The jacket should be about 200°.
2. 33% is used for power, 33% is unused and 33% is handled by the cooling system.
3. The heat is transferred to the extremities of the engine.
4. Because of its rapid heat conductivity.
5. To increase the surface area of the engine.
6. To permit rapid air exchange.
7. Always make sure the water is clean and free from mineral deposits.

13895

8. Both lime and rust are poor heat conductors.

9. It causes hot spots and may cause distortion of engine parts.

10. It causes rapid and uneven cooling which may crack the head or block.

Ref. Purvis, pages 97-101.

Teaching Suggestions: Have students examine the case of an air cooled engine. Have them figure a problem to determine the increase in surface area gained by using fins.

13896

Problem Area: Small Gas Engines

Problem: Repair

Job: Checking Piston and Cylinder Tolerance

Motivation: Poor fitting parts allow excessive oil consumption and loss of horsepower. Air cleaners play a very important role in maintaining engine life.

Study Questions:

1. What is the first step prior to the removal of the piston?
2. What precautions should be taken when removing the piston?
3. How do you check tolerance on pistons?
4. Where does the cylinder wear most?
5. How do you determine clearance?
6. What should the skirt clearance measure?

Summary of Information:

1. Carbon should be removed from the top of the cylinder. In some engines it will be necessary to remove a ridge above the piston before removing the piston.
2. A. Do not drive on any part if parts are to be re-used.
   B. Mark piston, rod, and cap for reuse.
   C. Inspect all parts of damage and measure for wear.
3. A. Measure skirt clearance.
   B. Measure top land clearance.
   C. Measure cylinder wall from top to bottom.
   D. Check to see that all carbon is removed from ring grooves.
4. On the thrust side (when the piston is pushing against compression).

13897

5. Cylinder diameter - 2.3755
   -Skirt diameter - 2.3695
   Skirt clearance - .0060

6. This will vary from make to make. Always check operators manual.

Ref. Clinton Engines or Small Engines Service Manual; Purvis, pages 59-80.

Teaching Suggestions: Have students study the parts of the piston on the following two pages.

13898

A. Land
That part of the piston above the top ring or between ring grooves.

B. Compression Distance
The distance from the center of the pin hole to the top of the piston.

C. Piston Head
The top piston surface against which the combustion gases exert pressure.

D. Piston Pin
Connections between the upper end of the connecting rod and the piston.

E. Skirt
That part of the piston located between the first ring groove above the pin hole, and the bottom of the piston.

F. Pin Hole
An opening through the piston skirt to carry the piston pin.

G. Piston Pin Bushing
A bushing fitted between piston pin and piston pin hole to obtain a better bearing material.

H. Oil Ring Groove
A groove cut into the piston around its circumference, at the bottom of the ring belt or at the lower end of the piston skirt.

J. Groove Root Diameter
Diameter of the piston measured at the bottom of the groove.

K. Land Diameter
Diameter of the land being measured.

L. Land Clearance
The difference between the diameter of the land and cylinder diameter.

M. Skirt Clearance
The difference between piston skirt diameter and cylinder diameter. (M shows ½ the total clearance)

Figure 16

13899

Ring Width

The distance from top to bottom of the ring measured in fractions of an inch. See illustration below.

Side Clearance

Axial or "up and down" clearance between the side of the ring and the ring groove. See illustration below.

Back Clearance

Clearance between the back side of the ring and the bottom of the ring groove when both piston and ring are centered in the cylinder. See illustration below.

Figure 17

13900

Problem Area: Small Gas Engines

Problem: Repair

Job: Honing and Deglazing Cylinders

Motivation: How does cylinder wear take place? What's wrong if the engine still uses oil after installing new rings?

Study Questions:

1. What is the purpose of "deglazing" cylinders?
2. What grit stone should be used?
3. What precaution must be taken when honing?
4. Should oil be used in the honing operation?
5. How often should the cylinder be checked?
6. What tool is used to remove large amounts from the cylinder?
7. What should be used to clean the cylinder after honing is completed?
8. Why should solvent or gasoline not be used?

Summary of Information:

1. A. To remove the vertical marks in the cylinder.

   B. To straighten the cylinder from top to bottom.

   C. To correct a small amount of out of round.

   D. To remove any foreign materials.

   E. To cross-hatch and enable cracks to be seen.

2. 150 grit - 240 grit.
3. Always start hone in the narrowest point of the cylinder (usually the crankcase end).
4. Only on "wet stones". Oil should not be used on the "dry-stone" type.
5. After every few seconds when near the desired measurement.

13901

6. A boring bar should be used to remove large amounts.

7. A. Hot soapy water.

   B. Rag soaked in cylinder oil.

8. It will remove the oil from the cylinder and leave the metal chips and foreign material in the cylinder.

Ref. Purvis, pages 127-131; Briggs and Stratton Repair Instructions II, page 41.

Teaching Suggestions: Demonstration next page.

13901

13902

ASSIGNMENT:

From the pictorial drawings shown below, draw a front and top view. Dimension fully.

1.

GEAR BLANK A-6B

2.

PINION SHAFT BEARING A-6C

From the pictorial drawing shown below, draw a front and right-side view.

3.

PINION SHAFT B-8B

4.

SHAFT STOP B-8C

Problem Area: Small Gas Engines

Problem: Repair

Job: Honing and Deglazing Cylinders

Demonstration:

Materials needed: micrometer, cylinder hone, honing oil, drill press, metal jig (see drawing next page on cylinder holder) and a level.

Procedure:

1. Thoroughly clean the cylinder to be honed.

2. Secure cylinder to jig and make sure it is level (See Figure 18).

Figure 18
Courtesy Briggs and Stratton

3. Oil surface of drill press table, then set block and jig on table. Be sure the block is free to move so the hone will stay in alignment.

4. Determine what oversize the cylinder is to be honed. Glaze can be removed in the same manner except that it requires a lot less time.

5. Set drill to operate between 300 and 700 R.P.M.

13904

13903

BRIGGS & STRATTON CORP.

CYLINDER HOLDER

FOR RESIZING 6, 8, AND 14 CU. IN. ALUMINUM ALLOY CYLINDERS

Figure 19

13904

6. Set hone in cylinder and set drill stops so that hone will not extend over 3/4-inch from top or bottom. See Figure 18 on page 74.

7. Place hone in middle of bore and tighten until stone fits snugly. Start drill at bottom and hone (adding oil to lubricate hone) from bottom and finishing at top. Change from rough to finishing hone when within .0015-inch. To give cross-hatch pattern move the hone from top to bottom rapidly for the last few seconds (See Figure 20).

Figure 20
Courtesy Briggs and Stratton

8. Check cylinder size frequently.

9. Clean the cylinder with solvent, and then wash with soap and water. Emphasize removing all of the grit and metal cutting that are embedded in the cylinder wall.

10. Check cylinder bore with ring, measuring the ring gap after the block has had time to cool. It is usually desirable to hone .0005-inch larger than the desired reading because the cylinder wall will shrink as it cools.

Ref. Briggs and Stratton Repair Instruction II, page 41.

13905

Problem Area: Small Gas Engines

Problem: Repair

Job: Installation of Rings

Motivation: What happens when you buy a set of 40 thousandths oversize rings for an engine. You have to get these particular rings from Chicago. Then by improper methods of installation you break one ring.

Study Questions:

1. What is the purpose of rings?

2. Do the rings press against the cylinder walls?

3. What is the primary problem in piston rings?

4. What is ring blow-by?

5. When is blow-by the greatest problem?

6. What are the functions of each of the rings?

7. Show the typical piston ring installation.

Summary of Information

1. A. To prevent loss of compression.

   B. To control the loss of oil.

2. Yes, about 8-12 pounds of pressure.

3. That pistons, rings, and cylinders warp at operating temperatures.

4. The compression and explosion pressure can go past the ring.

5. When the cylinder is out-of-round.

6. A. Compression ring; usually a plain ring, rectangular in cross-section or with a groove cut in the inner top corner (Figure B-42 p. 71, Purvis).

   B. Compression ring; usually a plain ring and may also be used to control oil.

   C. Oil rings; used to control the loss of oil and may be in several shapes and designs. (Figure B-44, p. 72, Purvis)

13906

7. See illustration below (Figure 21)

   A. Full face contact - pressure over a large area.

   B. Narrow contact surface - high pressure on the area. Seats quickly.

   C. Two narrow contacts, scrape oil from cylinder wall. These may be in combination.

Ref. Purvis, pages 63-78.

Teaching Suggestions: Demonstrate proper technique.

Figure 21

13907

Problem Area: Small Gas Engines

Problem: Repair

Job: Installation of Rings

Study Questions:

1. Why must the ring groove be clean?
2. How can you clean the ring grooves?
3. In what order should the rings be put on the piston?
4. What is the next step in installing rings?
5. When should rings be replaced?
6. What can be done if the ring fits too tight?
7. What type of lubricant should be used before inserting the piston?

Summary of Information:

1. Often the ring must work in the groove in order to prevent blow-by.
2. A. Carbon removal tool.

   B. Broken ring.
3. All should be put on from the top of the piston down, which means oil ring first, scraper second, and compression ring last.
4. Check groove clearance by use of a thickness gauge. Tolerance should be compared to service clearances.
5. If ring clearance is excessive, it will be necessary to replace rings.
6. The ends of the ring may be filed off, but it is usually better to check the cylinder bore and order the correct size or replace with chrome ring designed for wear exceeding standard but under oversize.
7. A clean light oil should be used.

Ref. Purvis, pages 63-78.

Teaching Suggestions: See demonstration plan on page 83.

13908

Problem Area: Small Gas Engines

Problem: Repair

Job: Checking and Correcting Crankshaft End Play

Demonstration:

1. Fasten a dial indicator on sump so that indicator touches the crankshaft. Turn crankshaft a number of times if indicator shows more than .002 discard crankshaft. The crankshaft may also be checked by placing it between centers on a lathe and mount dial indicator in tool post.

2. Check all points of the crankshaft for wear with a micrometer. Check manual for discard sizes.

3. Reassemble crankshaft into sump and block.

4. Check crankshaft end play with a dial indicator. End play should range from .002 to .008.

5. Follow procedure on page 53 of Briggs and Stratton Repair Instructions II, if end play is beyond these limits.

Ref. Briggs and Stratton Repair Instructions II, page 53.

13909

13910

Problem Area: Small Gas Engines

Problem: Repair

Job: Replacing Main Bearings

Demonstration:

1. Drive out old bushing with bushing driver 19124 and support 19123. If there is no bushing then ream cast as follows:

   A. Place pilot in opposite bearing.

   B. Assemble sump to block.

   C. Guide bushing should be placed in oil seal slot on side.

   D. Assemble 19099 reamer on pilot 19096.

   E. Place pilot through guide bushing pilot on opposite side and begin to ream in a clockwise motion with steady pressure until reamer goes all the way through. Do not back the reamer out. To remove reamer separate sump from block. Ream dry.

   F. Clean parts with solvent.

2. Stake mark in hole with chisel.

3. Insert bushing with driver. Use crankcase support, make sure oil holes are aligned, drive bushing in until flush.

4. With a blunt chisel drive a portion of the bushing into the notch previously made in 2 above.

5. Ream with finish reamer 19095 same as in (1e) except that a lubricant should be used.

6. Replace oil seal.

Ref. Briggs and Stratton Repair Instruction II, page 55-60.

Teaching Suggestions: See page 82 for cylinder vise support.

C0CC1

13910

Briggs & Stratton Engine

SMALL ALUMINUM CYLINDER VISE SUPPORT

Make From 1/4" Steel Plate (Welded)

Figure 22

13911

steel

Problem Area: Small Gas Engines

Problem: Repair

Job: Installing Rings and Pistons

Demonstration:

1. Inspect piston to be sure that oil holes are open and that ring grooves are clean.

2. Measure all wearing parts of the pistons.

3. Place ring into cylinder and push part way down with piston. Measure ring gap and compare against rejection table in Briggs and Stratton Repair Manual.

4. Use ring expander and install oil ring first, then center compression ring and then top ring. Emphasize following the instruction that come with the rings.

5. Place piston in ring compressor and tighten compressor.

6. Place piston on top of cylinder and push into cylinder. Check to see that rod is in correct alignment with crankshaft. Do not hammer or beat piston into cylinder as this will break rings. Thumb pressure should be adequate.

8. Install rod cap (alignment marks should be observed) and torque according to manual.

9. Bend locking lugs against rod bolt heads.

Ref. Briggs and Stratton Repair Instructions II, page 45.

13912

UNIT VII - WORKING DRAWINGS

Sketching Pictorials — Lesson 5

OBJECTIVE: To practice visualization by sketching freehand pictorials.

RELATED INFORMATION:

A draftsman is never adequately equipped without the ability to sketch pictorially. Before he can produce any working or orthographic drawings, he must be able to visualize the shape of an object. Every idea in the design or invention of a piece of machinery comes into the mind in pictorial form; preliminary sketches made in this form preserve the idea as visualized.

A pictorial drawing is often required if the orthographic drawing is difficult to read. Learning to sketch pictorially early in training not only gives you the opportunity to apply this knowledge when employed as a draftsman, but will also prove conclusively that you can visualize the orthographic drawing. Pictorial sketches need not be artistically executed, but should be drawn proportionally correct.

QUESTIONS:

1. Why learn to sketch pictorially?
2. Must sketches be artistic?
3. Would a soft or hard drawing pencil be better for sketching?
4. Explain how the ability to sketch helps the designer.
5. Is a draftsman adequately equipped without the ability to sketch pictorially? Explain.

ASSIGNMENT:

The isometric method of sketching is most commonly used. For practice, sketch freehand on cross-section paper the following three problems. Note the orthographic drawings given and then follow the steps suggested for sketching.

138

Problem Area: Small Gas Engines

Problem: Repair

Job: Reassembly

Demonstration:

1. Insert tappets, crankshaft, and cam gear. (lubricate all parts)
2. Assemble piston and connecting rod and install.
3. Secure oil slinger and install sump. Adjust the crankshaft end play.
4. Set valve clearance.
5. Replace valve assembly.
6. Assemble coil, governor blade and ignition cable.
7. Install points and condenser.
8. Adjust points.
9. Install breaker point cover, seal wires with gasket sealer.
10. Install flywheel.
11. Adjust air gap.
12. Check ignition by checking spark.
13. Install air cleaner.
14. Place cylinder head and gasket in place and tighten to proper torque.
15. Install spark plug.
16. Tighten muffler if it has been removed.
17. Assemble carburetor and linkage.
18. Install governor.
19. Install blower housing.
20. Connect fuel lines.
21. Fill crankcase with oil.

13914

13913

22. Fill gas tank.

23. Start engine.

24. Re-torque head.

25. Make fine adjustments on carburetor and governor.

26. Fill air cleaner.

27. Paint engine.

28. Apply decals.

13914

Problem Area: Small Gas Engines

Problem: 4-cycle Engines

Job: General Structure

Motivation: We should understand the principles of 4-cycle operation by now and we can repair 2-cycle engines. What additional parts are involved to be repaired in the 4-cycle engine?

Study Questions:

1. What are two main types of 4-cycle engines?
2. What is different about the structure of the 1 cylinder, 4-cycle engine and the 1 cylinder 2-cycle engine?
3. What is the purpose of the camshaft gear?
4. What does the camshaft on a single cylinder engine consist of?
5. What type engine valve arrangement is common in 1 cylinder engines?

Summary of Information:

1. Air cooled and water cooled.
2. The 4-cycle contains a camshaft and valves. The oiling is accomplished by regular oil in the crankcase and usually using the splash method. The carburetor is of a different type.
3. To engage the camshaft with the crankshaft.
4. There are 2 lobes. One in position to operate the intake valve and one to operate the exhaust valve.
5. L head design.

Ref. Purvis, pages 12-18, 35-36, 51-52.

Teaching Suggestions: Have camshaft and gear for observation.

13915

Problem Area: Small Gas Engines

Problem: 4-cycle Engines

Job: Repair of Camshaft

Motivation: Why is it so important that valves work properly in a 4-cycle engine?

Study Questions:

1. What similarities and differences would you expect in repairing a 4-cycle engine as compared to a 2-cycle engine?

2. List the parts and what to check for in repairing the valve system.

3. How can the valves be repaired?

4. Where is the automatic spark advance located?

5. How can you tell when you have the cam gear in the correct position in relation to the crankshaft?

Summary of Information:

1. Everything learned about repair of cylinders, pistons, crankshafts, and carburetors apply to both. Camshaft and valve parts are only in the 4-cycle engine.

2. A. Valve seats - pitting or burning.

   B. Valves - pitting or burned edges or warpage.

   C. Valve guides - worn too loose.

   D. Tappet - flat face should be checked for wear. These usually do not need replacing.

   E. Gears - excess wear.

   F. Camshaft bearings - looseness.

3. If they are badly burned or worn, it is probably better to replace them and lap the new ones by using a grinding compound. Valve seats may be replaced if they are bad enough. Valves may be refaced or valve seats reground with special equipment.

4. In the camshaft gear.

13916

5. There is a timing mark on both gears. These should be matched. If there is no mark, they should be marked before disassembly.

Ref. Purvis, pages 51-52.

Teaching Suggestions: Demonstrate procedure of checking and repairing valve and camshaft assembly. Have students spend several days in shop repairing 4-cycle engines.

13917

Problem Area: Small Gas Engines

Problem: Trouble Shooting

Job: Oil Consumption and Overheating

Motivation: It's common to say an engine needs rings when it is using oil. This may or may not be so, but it usually needs other things too. You wouldn't want to tear an engine down, put in rings and put it back together only to have it continue to use oil.

Study Questions:

1. Make a list of things that can cause high oil consumption.
2. How can you find out what things are the cause?
3. How can overheating cause increased oil consumption?
4. Make a list of factors that can cause engine overheating.
5. What process is used to determine the causes?

Summary of Information:

1. Worn cylinder bores.
2. Tapered cylinder bores.
3. Distorted cylinder bores.
4. Worn pistons.
5. Collapsed pistons.
6. Improperly fitted pistons.
7. Stopped up piston drain holes.
8. Worn piston ring grooves.
9. Worn piston rings.
10. Wrong size piston rings.
11. Incorrectly installed piston rings.
12. Rings too tight in ring grooves.
13. Improperly fitted rings.
14. Clogged piston ring slots.

13918

15. Worn piston pins.

16. Worn piston pin bushings.

17. Bent or twisted connecting rods.

18. Worn connecting rod bearings.

19. Loose connecting rod bearings.

20. Excess side clearance in connecting rod bearings.

21. Worn main bearings.

22. Loose main bearings.

23. Excess crankshaft end play.

24. Bent crankshaft.

25. Out-of-round crankshaft journals.

26. Damaged crankshaft end play.

27. Damaged crankshaft oil slingers.

28. Worn intake valves.

29. Worn intake valve guides.

30. Worn camshaft bearings.

31. Worn camshaft journals.

32. Engine overheating.

33. Clogged water jackets.

34. Oil level too high.

35. Excessive oil pressure.

36. Clogged oil return from valve chamber.

37. Clogged oil return from timing gear case.

38. Clogged breather pipe.

39. No baffle in breather pipe.

40. Broken oil line.

13920

13919

41. Oil leaking past front and rear main bearings.

42. Cracked crankcase.

43. Crankcase gasket leaks.

44. Defective crankshaft seals.

45. Leaking timing gear case gasket.

46. Leaking valve cover gasket.

2. By tearing the engine apart and checking possible causes.

3. By oil vaporization at high temperatures and by causing the cylinders to get out of round.

4. 1. Scale and rust in cylinder head.

   2. Scale and rust in cylinder block water passage.

   3. Cylinder head gasket blown.

   4. Incorrect cylinder head gasket.

   5. Cylinder block hot spot.

   6. Worn water pump impeller or housing.

   7. Sheared impeller pin or key.

   8. Clogged muffler

   9. Valve timing late.

   10. Worn timing chain.

   11. Leaking valves.

   12. Ignition timing late.

   13. Defective ignition spark advance.

   14. Carburetor mixture too rich.

   15. Leaking piston rings.

   16. Overload engine.

   17. Low engine oil level.

13920

18. Stiff engine (after overhaul).

19. Obstructed air passages (or dirt on air cooling fins).

20. Bent fan blades.

21. Worn fan belt.

22. Loose fan belt.

23. Worn drive pulleys.

24. Undersupply of coolant.

25. Foaming of coolant.

26. Leaking cylinder head.

27. Leaking cylinder head gasket.

28. Leaking cylinder block.

29. Leaking expansion plugs.

30. Leaking water pump housing.

31. Leaking water pump shaft.

32. Leaking water pump gasket.

33. Leaking drain cocks.

Ref. Purvis, pages 115-118.

Teaching Suggestions: Have students solve verbal trouble shooting problems; then have them actually determine the trouble in some engines.

13921

13955

Problem Area: Small Gas Engines

Problem: Trouble Shooting

Job: Engine Noise

Motivation: Some mechanics can usually tell which bearings an engine needs by listening to it run.

Study Questions:

1. What methods may be used in determining what is causing a knock?

2. What are the characteristics of a knock from each of the following sources?

   A. Connecting rods.

   B. Piston pins.

   C. Main bearings.

   D. Flywheel.

   E. Crankshaft end play.

   F. Timing gears.

   G. Piston slap.

   H. Ring noise.

   I. Valves.

3. What if all of these are all right and the engine still knocks?

Summary of Information:

1. Listening for certain tones in the knock or characteristics of the sound itself. Using a kind of stethoscope to determine the location of the knock. To observe the running conditions necessary to hear the knock.

2. A. Will be heard at all speeds. One rod will be distinct, several will cause a clatter.

   B. When a stethoscope is used, the knock is loudest on the block. Shorting a spark plug will change the intensity of the knock.

   C. A bump which may be located by shorting out plugs. Loudest when lugging. Heavier and duller than connecting rod knock.

13921

13922

PROBLEM 1

PROBLEM 2

PROBLEM 3

1389

D. Similar to main bearing except not affected by shorting out spark plug. Shut off the engine and turn it on again as it is about to stop.

E. Sharp intermittent rap or knock.

F. Need a stethoscope to determine location as it occurs at all speeds.

G. Decreases as engine warms up.

H. Clicking noise.

I. Use a stethoscope. Check valve tappet clearance.

3. These knocks are due to misalignment or endwise motion of parts.

Ref. Purvis, pages 118-121.

Teaching Suggestions: Have students work with engines having some of these things wrong with them. Demonstrate use of the stethoscope.

13923

Problem Area: Small Gas Engines

Problem: Trouble Shooting

Job: Ignitions

Motivation: If you knew that the spark plug was not firing, what would you do to correct it?

Study Questions:

1. How must you test most parts of the ignition system?

2. What might be the cause of arcing at the points?

3. What might be wrong causing only a weak spark and the engine will not start?

4. How could you detect a cracked spark plug, a bad wire, or a short circuit anywhere in the system?

Summary of Information:

1. A special ignition testing device may be used.

2. A bad condenser.

3. A bad magneto, bad connection somewhere, or an improperly adjusted plug.

4. You'll get a shock when you touch a bad wire with the engine running. A weak spark may indicate a cracked plug or short circuit after all other possible causes are checked.

Ref. Purvis, pages 182-193, 205-210.

Teaching Suggestions: Demonstrate methods of checking ignition system. Review page 27 and 28.

13924

13924

Problem Area: Small Gas Engines

Problem: Trouble Shooting

Job: Carburetor Trouble

Motivation: Have you ever seen ice form on a carburetor when the engine is running? Did you ever have trouble with an engine that would run all right until you closed the throttle to idling, then die?

Study Questions:

1. What causes carburetor icing?
2. What does it do that causes trouble?
3. If the engine does not run, would you check the carburetor first?
4. How can a carburetor be cleaned?
5. Make a list of possible causes for poor carburetor performance.
6. Make a list of things that might cause poor idling.
7. Make a list of things you would check if the carburetor floods.

Summary of Information:

1. Certain weather conditions. Usually 28-55°F and 65 to 100 per cent humidity. Rapid vaporization of the fuel lowers the temperature, then vapor in the air freezes.
2. Ice forms around the throttle so that it does not allow proper flow of fuel from the idling jets.
3. No. Check the ignition system, compression, and the fuel supply. If these are all right, then check the carburetor.
4. Use a carburetor cleaning solution. Take the carburetor apart and clean and inspect each part.
5. A. Air leaks at carburetor or manifold.

   B. Clogged fuel lines.

   C. Defective fuel pump.

   D. Incorrect fuel level.

   E. Clogged fuel screen.

13926

13925

F. Dirt in carburetor jets and passages.

G. Damaged or wrong size main metering jet.

H. Worn idle needle valve and seat.

I. Loose jets in carburetor.

J. Defective gaskets in carburetor.

K. Worn throttle shaft.

L. Leaking vacuum lines to accessory equipment.

6. A. Incorrect adjustment of idle needle valve.

B. Incorrect float level.

C. Sticking float needle valve.

D. Defective gaskets in carburetor.

E. Defective gaskets between carburetor and manifold.

F. Loose carburetor to manifold nuts.

G. Loose carburetor to block nuts.

H. Idle discharge holes partly clogged.

I. Loose jets in carburetor.

J. Leaking vacuum lines to accessory equipment.

7. A. Fuel level too high.

B. Stuck float needle valve.

C. Defective gaskets in carburetor.

D. Cracked carburetor body.

E. Excessive fuel pump pressure.

Ref. Purvis, pages 139-151.

Teaching Suggestions: Let students determine what is wrong with a carburetor and repair it.

13926

13929

Problem Area: Small Gas Engines

Problem: Governors

Job: Principles of Operation

Motivation: How can a governor control the speed of an engine?

Study Questions:

1. What are the two types of governors used on Briggs and Stratton engines?

2. How are the two types different in operation?

3. What is the basic purpose of a governor?

4. How can the speed of the engine be changed by the governor?

5. What is meant by governed speed?

Summary of Information:

1. Mechanical and air vane.

2. The mechanical governor has counter weights operating by centrifugal force, which tend to hold the throttle closed, this force tends to increase as the engine speed increases. This force is off set by a governor spring where tension is increased or decreased by the hand throttle setting.

   The air vane governor works off the air current coming off the vanes of the flywheel. This air current over-rides the spring tension in the same way as the mechanical governor.

3. To maintain a desirable engine speed, with varying loads.

4. The governed speed is changed by varying the spring tension.

5. When the force opposing the governor spring and the force of the spring are equal or balanced.

Ref. Repair Instruction II, ppages 73-87.
Purvis, pages 113-114.
Briggs and Stratton General Theories

Teaching Suggestions: Demonstrate the operation of both types of governors and how they are adjusted.

13928

13927

Problem Area: Small Gas Engines

Problem: Starters

Job: Repair

Demonstration:

New or old style starter assemblies can be identified by the spring in rewind starter housing. Old style spring has a hook on the end for attaching to the pulley. New style has a tapered end which is inserted into a slot in the pulley. Repair procedures are the same except where noted.

1. Cut knot at starter pulley and remove rope.

2. Remove the spring by grasping outer end of spring and pull out of the pulley as far as it will go. Bend the retaining tangs up and remove pulley and spring. Clean the entire assembly and coat with light oil.

3. Installation of spring.

New Style

Insert spring through slot in blower housing, and hook the end of the spring into pulley hub. Place dab of grease on under side of pulley. Place pulley in housing and carefully bend tangs to within 1/8 inch of the pulley.

Old Style

Insert end of the spring with straight hook through housing above slot. Hook the end of the spring into the slot of the pulley. Push spring retainer into place with split portion of retainer opposite spring end.

4. The procedure for the rest of the installation is the same for both the old and the new style rope starter.

   A. Put the starter tool into the center of the pulley hub. See Figure 23 and 24 page 101.

   B. Place screwdriver through one of the holes at the top end of the square tubing and wind the pulley 13 1/4 turns, counter-clockwise.

   C. Hold the tool with your hand and remove the screwdriver and relocate the screwdriver through one of the holes at the bottom of the tubing.

13928

D. Pierce end of rope with rope inserter tool (see Figure 24 page 101) and place rope through hole in pulley.

E. Remove rope inserter and tie knot in the end of the rope.

F. Hold the rope and remove steel tubing.

G. Rope should not rewind into pulley.

Ref. Briggs and Stratton, Repair Instruction II, page 62.

13929

13930

Figure 23
You can make a tool like the one in the upper left hand corner from a 9 inch section of 3/4 inch square tubing, with holes drilled 1 1/2 inches from either end.

Figure 24
A rope inserter tool may be made from piano wire pounded flat at one end as shown.

13930

STARTER TANG TOOL

Figure 25

1. Material required is 7 1/2" length of 5/8" square stock steel.

2. Drill 3/32" hole as indicated in top drawing.

3. Cut and grind to dimensions shown in bottom drawing.

The above drawing is for special starter tang tool for lifting tangs on Windup Starters. See Briggs and Stratton Repair Instructions II, page 63.

Starter Tang Tool
Scale - 12" = 1' - 0"
Date - 6 July 1965

13931

13931

Problem Area: Small Gas Engines

Problem: Repairing Engines

Job: In What Order Should Repairs be Made?

Procedure:

Students should use Briggs and Stratton Repair Instructions step by step procedure for repair of their engines.

1. The valve repairs should be done in the following order:

   A. Clean parts.

   B. Replace valve seats if they are needed.

   C. Install new valve stem bushings if they are needed.

   D. Reface valve seats, and narrow to correct specifications.

   E. Grind valves.

   F. Lap valves.

2. The following procedures can be done anytime during the repair procedure. These repairs can be done at times when students are waiting to use valve repairing tools.

   A. Resizing cylinder.

   B. Replacing main bearings and oil seals.

   C. Rebuild carburetor.

   D. Replace breaker point bushings.

   E. Repair starter assembly.

   F. Repair threads.

13932

13931

OBJECTIVE:

To learn the usage and application of auxiliary views.

RELATED INFORMATION:

An auxiliary view is defined as an orthographic projection on a plane perpendicular to one of the principal planes of projection but inclined to the other two (Fig. 1).

The chief reason for using an auxiliary view is to show the true shape of a slanting surface. If we used the conventional three views - front, top and side - the slanted surface would appear distorted and not true in length. Thus the edge view of the auxiliary plane therefore should be parallel to the edge view of the slanting surface. Holes or rounded surfaces which appear round in normal views will appear elliptical in shape in other views. (Fig. 2).

Overhaul Tool List - Small Gas Engines

The following list is divided into three parts. Part I lists essential tools to completely overhaul the Briggs and Stratton Engines with 6 and 8 cubic inch displacement. Part II lists those tools which are not absolutely necessary, but add to the ease and convenience of engine overhaul. Part III could be classed as essential supplies. Prices are effective September 1, 1968 and subject to change without notice.

Part I

Number of Tools	Name of Tool	Company	Number	Price
1	Adj. Valve Seat Cutter Kit	Neway	102A	34.50
1	Cylinder Hone Set	Ammco	3950	58.50
1	Cylinder Hone Stone Roughing Set	Ammco	3951	5.30
1	Cylinder Hone Stone Finishing Set	Ammco	3952	5.30
2	Cylinder Hone Stone Aluminum Set	Ammco	3955	5.30
1	Piston Ring Expander	Ammco	8332	2.80

ABSTRACT - Developed to help students learn
the language of aircraft pilots and
astronauts this document consists of a
teaching guide for an aerospace
communications laboratory plus a student
workbook. The teaching guide lists
educational objectives and includes
information on: (1) Aerospace Messages, (2)
How Numbers are Spoken, (3) Aircraft Call
Signs, (4) Teaching Aids, (5) Role Playing,
(6) The International Phonetic Alphabet, and
(7) Aerospace Words and Phrases. The student
workbook includes exercises covering call
signs, the international phonetic alphabet,
and the communication of messages. A glossary
is also included. (JS)

TEACHING GUIDE FOR
AN
AEROSPACE COMMUNICATIONS LABORATORY

I. INTRODUCTION

Aviation and space are affecting the daily lives of more and more people. This impact of aerospace is growing rapidly. Young people especially have an urgent requirement to develop the knowledge, skills, and attitudes that will enable them to percieve the effects of aviation and space exploration on our way of life.

The language of aerospace is unique. It is also fascinating to most people. This teaching guide for an aerospace communications laboratory is designed to help students learn to speak the language of aircraft pilots and astronauts -- the language of aerospace.

II. OBJECTIVES

To create teaching-learning experiences that will:

1. Motivate students to develop, through active participation, essential communication skills.

2. Provide an environment for educational leadership in the communication arts.

3. Improve vocabulary, develop capabilities of expression, and extend communications horizons.

4. Improve methodology in the communication arts by utilizing multimedia educational techniques.

5. Introduce the interrelationships between aviation and space communications and other subjects in the school curriculum.

6. Interpret the effects of aviation and space exploration on the social, economic, political, and cultural structure of the world.

13940

III. AEROSPACE MESSAGES

Aerospace messages are transmitted and received by aircraft pilots, control tower operators, astronauts, and space capsule communicators. Student pilots flying light airplanes, control tower operators at small airports, airline captains in big jets, air traffic controllers at large metropolitan airterminals, and astronauts in space capsules all rely on aerospace communications to transact their "business."

Messages are sent while air and space vehicles are on the ground and at altitudes ranging from a few feet to the apogees of space vehicle orbits. All aerospace communications have two things in common -- they are necessary and they are as brief and as clear as possible. Emergency messages receive priority.

The following sections of this guide explain how pilots and astronauts talk with each other and with radio stations on the ground.

IV. THE INTERNATIONAL PHONETIC ALPHABET

The International Phonetic Alphabet consists of 26 code words. Code words in the alphabet are used to represent single letters, to spell out groups of letters, or to make sure that difficult or unfamiliar words are understood. The code words in the phonetic alphabet are approved by the International Civil Aviation Orgainzation (ICAO). They are used worldwide in aviation and space communication.

Letter	Code Word	Pronunciation	Letter	Code Word	Pronunciation
A	Alfa	(AL-FAH)	N	November	(NO-VEM-BER)
B	Bravo	(BRAH-VOH)	O	Oscar	(OSS-CAH)
C	Charlie	(CHAR-LEE)	P	Papa	(PAH-PAH)
D	Delta	(DELL-TAH)	Q	Quebec	(KEH-BECK)
E	Echo	(ECK-OH)	R	Romeo	(ROW-ME-OH)
F	Foxtrot	(FOKS-TROT)	S	Sierra	(SEE-AIR-RAH)
G	Golf	(GOLF)	T	Tango	(TANG-GO)
H	Hotel	(HO-TEL)	U	Uniform	(YOU-NEE-FORM)
I	India	(IN-DEE-AH)	V	Victor	(VIC-TAH)
J	Juliett	(JEW-LEE-ETT)	W	Whiskey	(WISS-KEY)
K	Kilo	(KEY-LOH)	X	Xray	(ECKS-RAY)
L	Lima	(LEE-MAH)	Y	Yankee	(YANG-KEY)
M	Mike	(MIKE)	Z	Zulu	(ZOO-LOO)

13941

V. HOW NUMBERS ARE SPOKEN

Numbers spoken over the radio are pronounced to sound like this:

Number	Sound	Number	Sound
1	WUN	6	SIX
2	TOO	7	SEV-EN
3	TREE	8	AIT
4	FOW-ER	9	NIN-ER
5	FIFE	0	ZERO

Each number is pronounced individually. The number 55397 is spoken: FIFE FIFE TREE NIN-ER SEV-EN. When numbers are combined with letters of the alphabet, the phonetic code work for each letter is spoken. Y4395 is pronounced like this: YANG-KEY FOW-ER TREE NIN-ER FIFE.

VI. AEROSPACE WORDS AND PHRASES

Pilots, astronauts, control tower operatios, and space capsule communicators use these words and phrases to make sure that their communications are brief and easily understood:

Primary Words and Phrases

Word or Phrase	Meaning
OVER	I expect a reply from you.
ROGER	I have received and understand your last message.
WILCO	I will do as you direct. I will comply.
OUT	My message is ended. No reply is expected.
NEGATIVE	No, or that is not correct.
SAY AGAIN	Repeat what you said.
CORRECTION	An error has been made. The correct words are..... (give correct message).
SPEAK SLOWER	Speak slower.
STAND BY	Wait a few seconds, a delay is necessary.

13942

Secondary Words and Phrases

Word or Phrase	Meaning
I SAY AGAIN	I will repeat what I said.
GO AHEAD	Go ahead with your message.
THAT IS CORRECT	Correct.
HOW DO YOU HEAR ME	Tell me how you hear me.

VII. PARTS OF A MESSAGE

Each radio message has three parts. Each part is as brief as possible. These parts are the Call-Up, the Message, and the Ending.

The Call-Up

1. Identifies the caller and the receiver.
2. Determines that both persons can hear each other.
3. Sets the stage for communicating the message.

The Call-Up includes the call sign of the station being called, the words THIS is, the call sign of the caller, and the word OVER.

Example

Pilot: GALVESTON TOWER, THIS IS CESSNA AIT WUN FOW-ER WUN. OVER.

Tower: CESSNA AIT WUN FOW-ER WUN, THIS IS GALVESTON TOWER. OVER.

The Message

1. Gives or requests information as clearly and briefly as possible.
2. Allows the receiver to reply if necessary.

Example

REQUEST LANDING INSTRUCTIONS. OVER.

13942

13943

The Ending

1. Acknowledges receipt of a message.
2. Terminates radio contact.

The Ending includes the aircraft call sign, the word ROGER, and if the contact is to end, the work OUT.

Example

CESSNA AIT WUN FOW-ER WUN, ROGER. OUT.

Sample Message

Pilot: CLEVELAND TOWER, THIS IS BEECHCRAFT WUN AIT FOW-ER WUN. OVER.

Tower: BEECHCRAFT WUN AIT FOW-ER WUN, THIS IS CLEVELAND TOWER. OVER.

Pilot: CLEVELAND TOWER, THIS IS BEECHCRAFT WUN AIT FOW-ER WUN, FOW-ER MILES SOUTH AT WUN THOUSAND, LANDING AT CLEVELAND. OVER.

Tower: BEECHCRAFT AIT FOW-ER WUN, FOW-ER MILES SOUTH AT WUN THOUSAND CLEARED TO ENTER TRAFFIC PATTERN, RUNWAY WUN AIT. WIND WUN AIT ZERO DEGREES AT WUN TOO.

Pilot: BEECHCRAFT AIT FOW-ER WUN. ROGER. OUT.

Tower: CLEVELAND TOWER. OUT.

VIII. AIRCRAFT CALL SIGNS

Civilian Pilots

During the first contact with a ground station, the complete aircraft call sign is used. Civil aircraft pilots include the make or type name of their aircraft. This is followed by the aircraft's registration number.

Example

CESSNA WUN TOO TREE FOW-ER TANG-GO (Cessna Aircraft Number 1234T)

PIPER NIN-ER SEV-EN SIX ZERO (Piper Aircraft Number 9760)

13944

Airline Pilots

Airline pilots use the airline name. This is followed by the flight number.

Example

UNITED TOO FIFE (United Air Lines Flight 25)

DELTA WUN AIT (Delta Air Lines Flight 18)

Military Pilots

Military pilots frequently use the name of their Service followed by the last five numbers in the aircraft's serial number.

Example

AIR FORCE ("JET" when appropriate) FOW-ER FOW-ER NIN-ER TREE TOO (Air Force Aircraft Number 44932)

AIR FORCE TOO WUN TOO WUN SIX (Air Force Aircraft Number 21216)

After radio contact has been established, and when conditions allow, the call signs may be reduced to the aircraft type or make followed by the last three numbers or letters of the full call sign.

Example

CESSNA SIX TOO YANG-KEY (Cessna Aircraft Number 1262Y)

BEECH WUN TOO ZOO-LOO (Beech Aircraft Number 6812Z)

After contact has been definitely established, communication may be continued without further call-up or identification.

IX. SAMPLE MESSAGES

Aviation

1. PURPOSE: A pilot wishes to request taxi and takeoff instructions.

Pilot: BAKER GROUND CONTROL, THIS IS (call sign). OVER.

Tower: (Call sign), THIS IS BAKER GROUND CONTROL. OVER.

Pilot: BAKER GROUND CONTROL, THIS IS (call sign). REQUEST TAXI-TAKEOFF INSTRUCTIONS. OVER.

Tower: (Call sign), THIS IS BAKER TOWER. RUNWAY WUN AIT. WIND WUN SIX ZERO DEGREES AT WUN TOO. ALTIMETER TREE ZERO ZERO FOW-ER. TIME WUN FOWER TOO SIX. OVER.

13945

2. PURPOSE: A pilot in flight desired permission and instructions for landing at Baker Airport.

Pilot: BAKER TOWER, THIS IS (call sign). OVER.

Tower: (Call sign), THIS IS BAKER TOWER. OVER.

Pilot: BAKER TOWER, THIS IS (call sign), WUN TOO MILES WEST. REQUEST LANDING INSTRUCTIONS. OVER.

Tower: (Call sign), THIS IS BAKER TOWER. REPORT BASE LEG FOR RUNWAY WUN AIT. WIND WUN SEV-EN ZERO DEGREES WUN SIX.

Pilot: BAKER TOWER, THIS IS (call sign). ROGER. OUT.

3. PURPOSE: A pilot in the traffic pattern at Baker Airport, turning base leg, needs approval to land.

Pilot: BAKER TOWER, THIS IS (call sign). OVER.

Tower: (Call sign), THIS IS BAKER TOWER. OVER.

Pilot: BAKER TOWER, THIS IS (call sign), TURNING BASE LEG FOR LANDING ON RUNWAY WUN AIT. OVER.

Tower: (Call sign), THIS IS BAKER TOWER. CLEARED TO LAND RUNWAY WUN AIT. OVER.

Pilot: BAKER TOWER, THIS IS (call sign). ROGER. OUT.

Space

4. PURPOSE: The Gemini 4 crew gives the Capsule Communicator (Cap Comm) the go-ahead to resume the countdown.

Gemini 4: CAP COMM, THIS IS GEMINI FOW-ER. OVER.

Cap Comm: GEMINI FOW-ER, THIS IS CAP COMM. OVER.

Gemini 4: CAP COMM, THIS IS GEMINI FOW-ER. ALL SYSTEMS ARE GO. RESUME COUNTDOWN. OVER.

Cap Comm: GEMINI FOW-ER, THIS IS CAP COMM. ROGER. COUNTDOWN IS RESUMING AT T MINUS FIFE ZERO SECONDS AND COUNTING. OVER.

Gemini 4: CAP COMM, THIS IS GEMINI FOW-ER. ROGER. OUT.

13946

5. PURPOSE: Gemini 4 requests information about weather in the recovery area.

Gemini 4: CAP COMM, THIS IS GEMINI FOW-ER. OVER.

Cap Comm: GEMINI FOW-ER, THIS IS CAP COMM. OVER.

Gemini 4: CAP COMM, THIS IS GEMINI FOW-ER. REQUEST WEATHER DATA FOR RECOVERY AREA. OVER.

Cap Comm: GEMINI FOW-ER, THIS IS CAP COMM. WEATHER IN RECOVERY AREA IS GOOD. TREE FOOT WAVES. WIND AIT KNOTS. VISIBILITY WUN ZERO MILES. OVER.

Gemini 4: CAP COMM, THIS IS GEMINI FOW-ER. ROGER. OUT.

6. PURPOSE: Cap Comm advises Gemini 4 that the landing point is 20 miles long.

Cap Comm: GEMINI FOW-ER, THIS IS CAP COMM. OVER.

Gemini 4: CAP COMM, THIS IS GEMINI FOW-ER. OVER.

Cap Comm: GEMINI FOW-ER, THIS IS CAP COMM. YOUR LANDING POINT IS TOO ZERO MILES LONG. OVER.

Gemini 4: CAP COMM, THIS IS GEMINI FOW-ER. ROGER. OUT.

X. MICROPHONE TECHNIQUE

Proper microphone technique is important in aerospace communications. Correct radio procedures must always be observed. Messages should be spoken in a normal tone of voice.

Pilots should keep messages as brief as possible. They should not read back information to control towers except to verify or clarify instructions. Remember, other pilots are waiting to use the channel.

13947

XI. TEACHING AIDS

The following teaching aids are recommended:

1. Airport Model. Include runways, wind tee, and control tower. Construct with paper, cardboard, cloth, or other readily available materials.

2. Model Aircraft. Construct with note paper. Use directions in the MODEL AIRCRAFT LABORATORY pamphlet listed in the bibliography.

3. Model Spacecraft Center. Construct with note paper, cardboard, or other available materials.

4. Globe. Available in classroom or school library. Use desk lamp to cast shadows, show day and night, and visualize spacecraft orbits.

5. Bulletin Board. Display charts showing International Phonetic Alphabet and pronunciation of numbers, words, and phrases used in radiotelephone communications.

6. Classroom Exhibits. Use models, pictures, or cutouts of aircraft, space vehicles, tracking stations, control towers, or other air or space equipment.

7. Student Workbook. Available in quantity for use with this guide. Write to National Headquarters, Civil Air Patrol, Maxwell Air Force Base, Alabama 36112, for free copies.

8. Communications Trainers (Basic). Construct using two tin cans, waxed string, and buttons, as follows:

9. Communications Trainers (Tube). Use long paper tubes, such as mailing containers. Glue together short sections to provide desired length.

10. Communications Trainers (Electronic). Use modified tape recorders, walkie-talkies, or other electronic communications equipment.

11. Recordings. Obtain and use recordings of aviation and space radio communications.

12. Printed Message. Newspapers, magazines, and other publications print the entire text or selected parts of aerospace communications during special air and space events. Obtain and use these to stimulate additional interest.

13948

XII. TEACHING METHODS AND TECHNIQUES

Topic	Suggested Teaching Methods
International Phonetic Alphabet	Use INTERNATIONAL PHONETIC ALPHABET: A PROGRAMED LEARNING EXERCISE. (See bibliography.)
Code Word Pronunciation	Demonstration by teacher. Performance by students. Recitation. Test.
Aerospace Words and Phrases	Demonstration by teacher. Performance by students. Recitation. Test.
Pronunciation of Numbers	Demonstration by teacher. Performance by students. Recitation. Test.
Parts of a Message	Demonstration by teacher. Performance by students. Recitation. Test.
Message Procedure	Demonstration by teacher. Identification by students. Performance by students. Practice communications.
Aircraft Call Signs	Designation of students. Demonstration by teacher. Performance by students. Practice communications.
Microphone Technique	Demonstration by teacher. Practice communications.
Transmitting and Receiving Sample Messages	Demonstration by teacher. Designation of communicators. Performance by students. Evaluation by teacher.
Transmitting and Receiving Original Messages	Performance by students. Evaluation by teacher.

13949

XIII. ROLE PLAYING

Educational authorities agree that students learn best by doing. Role playing offers an excellent opportunity for students to project themselves into the roles of pilots, astronauts, control tower operators, and space capsule communicators.

A simple method of doing this is to assign each student a call sign and having each "report" or respond to roll call each day using aerospace communications procedures.

The following technique is suggested: Assign each teacher a call sign, such as BAKER TOWER. Assign each student a call sign, such as CESSNA WUN NIN-ER (roll number), followed by the initials of the student's first and last names. (CESSNA WUN NIN-ER GOLF HOTEL would be the call sign of student number 19 on the roll, whose name is George Holt.) Have the students respond to roll call using the above procedures.

As the course progresses and the students become more proficient, role playing may progress to include origination, transmission, and reception of simulated aerospace messages that stimulate additional interest and generate new motivation. Students should be encouraged to participate in role-playing activities to develop proficiency in the origination, transmission, and receipt of the following types of messages: (1) Pilot to Tower, (2) Astronaut to Capsule Communicator, (3) Tower to Pilot, (4) Capsule Communicator to Astronaut.

13951

INTRODUCTION TO AEROSPACE. National Headquarters, Civil Air Patrol, Maxwell Air Force Base, Alabama 36112. 1963 75¢

MODEL AIRCRAFT LABORATORY. National Headquarters, Civil Air Patrol, Maxwell Air Force Base, Alabama 36112. 1964. Free.

XV. GLOSSARY

Aerospace. The earth's atmosphere and the space above it.

Apogee. That point in an orbit that is most distant from the earth.

Base Leg. The segment of a landing pattern just before final approach.

Beechcraft. Aircraft manufactured by the Beech Aircraft Corporation.

Cap Comm. Space Capsule Communicator.

Cessna. Aircraft manufactured by the Cessna Aircraft Company.

Control Tower. A tower at an airport that is operated to regulate air traffic.

Piper. Aircraft manufactured by the Piper Aircraft Corporation.

Recovery. The act of retrieving a space vehicle after launch.

Runway. An airport surface used by aircraft to take off and land.

Taxi. Moving an aircraft on the ground, under its own power.

Tracking Station. A station set up to track an object moving through air or space.

Traffic Pattern. The routes above an airport that are followed by aircraft before landing and after takeoff.

Wind Tee. A large weather vane shaped like a "T" or like an airplane.

MICROCOPY RESOLUTION TEST CHART

NATIONAL BUREAU OF STANDARDS-1963-A

OBJECTIVE: To learn how to make and use revolved sections.

RELATED INFORMATION:

In machine drafting, sections play an important role in visualizing a part. Without sectional views it would be extremely difficult to illustrate a part clearly in a drawing, or, in many cases, impossible to understand a part at all. In the case of the support arm shown in Fig. 1, it would not be possible, from the two views shown, to know if the top of the web were rounded off or if it were rectangular. The revolved section clearly describes the top of the web and shows that it is rounded off.

FIG. 1

A similar condition exists for the link shown in Fig. 2. Without the revolved section, the part connecting the cylinders could be rectangular instead of elliptical.

AEROSPACE COMMUNICATIONS LABORATORY

I. MY CALL SIGN

My call sign is _____

II. AEROSPACE MESSAGES

As a pilot I will be talking with _____
(Teacher's Call Sign)

As an astronaut I will be talking with _____
(Teacher's Call Sign)

III. THE INTERNATIONAL PHONETIC ALPHABET

The code words in the International Phonetic Alphabet are:

A - _____	J - _____	R - _____
B - _____	K - _____	S - _____
C - _____	L - _____	T - _____
D - _____	M - _____	U - _____
E - _____	N - _____	V - _____
F - _____	O - _____	W - _____
G - _____	P - _____	X - _____
H - _____	Q - _____	Y - _____
I - _____		Z - _____

13954

IV. HOW NUMBERS ARE SPOKEN

Numbers spoken over the radio are pronounced to sound like this. (Write in the sound of each number. Pronounce each number aloud.)

Number	Sound	Number	Sound
1	_____	6	_____
2	_____	7	_____
3	_____	8	_____
4	_____	9	_____
5	_____	0	_____

V. AEROSPACE WORDS AND PHRASES

These words and phrases are used in air and space communications. This is what they mean:

Words and Phrases	Meaning
Over	_____
Roger	_____
Out	_____
Say again	_____
Wilco	_____
Correction	_____
Negative	_____
Speak slower	_____
Stand by	_____
I say again	_____
Go ahead	_____
That is correct	_____
Do you hear me	_____

13955

VI. PARTS OF A MESSAGE

Each radio message has three parts. The three parts are (A) the Call-Up, (B) the Message, and (C) the Ending.

(A) Example of a Call-Up

Pilot: "Galveston Tower, this is Cessna Ait Wun Too Wun. Over."

Tower: "Cessna Ait Wun Too Wun, this is Galveston Tower. Over."

Write two other Call-Ups here:

1. Pilot: _____

   Tower: _____

2. Pilot: _____

   Tower: _____

(B) Example of a Message

Pilot: "Galveston Tower, this is Cessna Ait Wun Too Wun. Request landing instructions. Over."

Tower: "Cessna Ait Wun Too Wun, this is Galveston Tower. Runway Wun Six. Over."

Write two other Messages here:

1. Pilot: _____

   Tower: _____

2. Pilot: _____

   Tower: _____

(C) Example of an Ending

Pilot: "Galveston Tower, this is Cessna Ait Wun Fow-er Wun. Roger. Out."

Tower: "Cessna Ait Wun Fow-er Wun, this is Galveston Tower. Out."

13956

Write two other Endings here:

1. Pilot: _____

   Tower: _____

2. Pilot: _____

   Tower: _____

V. AIRCRAFT CALL SIGNS

Civilian Pilots

Civilian pilots use the make of their aircraft and its certification number, like this:

"Cessna Nin-er Sev-en Six Zero" (This is Cessna Aircraft Number 9760.)

Write two more civilian pilot call signs here:

1. _____

2. _____

Airline Pilots

Airline pilots use the airline name and the flight number, like this:

"United Too Fife" (This is United Air Lines Flight No. 25.)

Write two more airline pilot call signs here:

1. _____

2. _____

13957

Military Pilots

Military pilots frequently use the name of their Service, followed by the last five numbers in their aircraft's serial number, like this:

"Air Force Wun Wun Too Wun Six" (This is Aircraft Number 11216.)

Write in here the call sign used by two other military pilots:

1. _____

2. _____

Student Call Signs

Your teacher has assigned each student a call sign. Write in the call signs of two other students here:

1. _____

2. _____

VI. SAMPLE MESSAGES

Here is a sample message from a pilot requesting taxi and takeoff instructions:

Pilot: "Baker Tower, this is Cessna Wun Wun Too Wun. Over."

Tower: "Cessna Wun Wun Too Wun, this is Baker Tower. Over."

Pilot: "Baker Tower, this is Cessna Wun Wun Too Wun. Request taxi and takeoff instructions. Over."

Tower: "Cessna Wun Wun Too Wun, this is Baker Tower. Cleared to runway Wun Ait. Wind Wun Six Zero degrees at Wun Tree. Over.

Pilot: "Baker Tower, this is Cessna Wun Wun Too Wun. Roger. Out."

Your Messages

Use your own call sign and write in here another message requesting information:

Pilot: _____

_____

13958

Tower: _____

_____

Pilot: _____

_____

Tower: _____

_____

Pilot: _____

_____

Use this space to write other types of messages as follows:

1. Pilot to Tower
2. Astronaut to Cap Comm
3. Tower to Pilot
4. Cap Comm to Astronaut

<u>Pilot to Tower</u>

1. Pilot: _____

_____

Tower: _____

ABSTRACT - Designed as a 1-semester course in aviation science, this teaching guide was developed by educators and aviation personnel as a means of teaching practical physical science to high school students. A secondary purpose of the course is to inform students of career opportunities available in this field. Arranged in 14 chapters, the guide outlines information on: (1) Power Plant, (2) Aerodynamics, (3) Basic Flight Instruments, (4) Airports, (5) Instrument Flying, (6) Flight Planning, and (7) Careers and Vocational Opportunities. Objectives and suggested teaching methods are listed for each chapter. A glossary, sources of teaching aids, and list of flight line operators in Montana are appended. (JS)

TO THE TEACHER

This course guide was formulated to serve those secondary schools wishing to offer a sound course in aviation science.

That such a course could be valuable is demonstrated by: (1) the fact that civil aviation has experienced a tremendous growth during the past few years, with future projections showing the growth trend will continue; (2) that a large number of young people now in school will earn their living in some segment of aviation; (3) that basic scientific principles can be more easily taught if placed in a context interesting to the student; (4) that citizenship in a society influenced so much by aviation requires some degree of understanding of what it involves.

The emphasis in this outline is not directed toward teaching the student to fly; indeed, the airplane will be used only as a laboratory tool in demonstrating certain learnings. Rather, the emphasis is on learning practical physical science.

The committee who developed this guide are:

Dr. Wesley Caspers, Dean of Education, Western Montana College, Dillon, Montana.
Mr. Robert Anderson, Science Instructor, Great Falls High School, Great Falls, Montana.
Mr. Wayne Hoffman, Science Instructor, Helena High School, Helena, Montana.
Mr. Ronald Kologi, Science Instructor, Shelby High School, Shelby, Montana, and instructor at Aviation Education Workshop, Montana State University, Missoula, Montana, in 1964.
Mr. William Young, Science Instructor, Broadus High School, Broadus, Montana.
Mr. Jack Hughes, Chief Pilot, Johnson Flying Service, Missoula, Montana, technical consultant.
Mrs. Mary Jo Janey, Supervisor of Aviation Education, Department of Public Instruction and Montana Aeronautics Commission, Helena, Montana. (As of '66 assoc'd w/Cessna Aircraft Co.)
Mrs. Imogene Peek, secretary to the committee, Helena, Montana.

In addition to developing the course guide, the committee made the following suggestions: (1) that it be offered at the 11th and 12th grade level; (2) that math requirements be at least a year of algebra, with some geometry desirable. It is a one-semester course.

Each chapter has its own objectives and varying suggestions for methods. The appendix contains film lists, bibliography, and glossary of terms, as well as other items of interest. An optional chapter has been included to cover career opportunities in aviation. The chapter arrangement was purposely designed to provide maximum motivational effect,

13966

and at the same time to be in logical sequence. Individual teachers may wish to modify the sequence to suit themselves.

The committee recognizes that use of the outline will reveal weaknesses, and it urges that teachers using the outline write their recommendations to the committee to be considered when the guide is put in final form.

Basic textbooks recommended for use in the course are: Fundamentals of Aviation and Space Technology, University of Illinois, Urbana, Illinois; Private Pilot's Handbook of Aeronautical Knowledge, Federal Aviation Administration, Washington, D. C. 20590.

Other resource material will be necessary. The starred items in the bibliography can be considered necessary classroom material, but need not be furnished to all students.

Other equipment needs will be noted in each chapter outline.

Now a word about the use of airplanes in this course. Maximum effectiveness of the course will be achieved by planned use of airplanes, the airport, and airport facilities through field trips, suggestions for which are made in the appropriate chapter outlines. These will be used as a community resource to enhance motivation. It will be noted that in the opening chapter an early visit to the airport with an orientation or familiarization ride in an airplane is strongly recommended. This visit and flight will provide the springboard for launching the succeeding chapters.

Schools will find local flight operators to be very cooperative in supporting activities connected with the course. Most will provide the flight portions at cost. It would be advisable to consult with the local operator well in advance of the course, as he may have valuable suggestions. A listing of most local operators will be found in the appendix.

Finally, the Supervisor of Aviation Education will be available to assist in any way possible.

The committee would like to acknowledge and commend the Montana Aeronautics Commission, whose financial assistance made the course guide possible. Thanks go also to the Federal Aviation Administration, the administrators of Great Falls Public High School, Shelby High School, Broadus High School, Helena High School, Western Montana College, and the Montana Aviation Trades Association for support and encouragement.

AVIATION SCIENCE

I. INTRODUCTION

Objectives: (1) To develop interest and a favorable attitude toward the course; to allay fears.
(2) To develop general familiarity with aircraft, with emphasis on personal flying.

Suggested Methods: Field trip to the airport.
Visual devices such as pictures, slides, films.

A. You probably can and probably should become a pilot.

1. Business and pleasure of flying

a. Speed and convenience
b. Extent of private plane use
c. Brief survey of occupational opportunities

2. Preparations for flying

a. Many similarities to an automobile (gas,oil,tires, mechanical inspections)
b. Major differences in the medium of air (wing, propeller,electrical systems)
c. Orientation rides, etc.

3. Taxi to the warm-up area

a. Warm-up check list
b. Communications with the tower (police function of the FAA)
c. The student and private pilot's license

4. One function of this course is to prepare for written FAA exam.

a. Nature of the exam
b. Relationship of examined knowledge to ability to fly

B. Know your aircraft

1. Advantages and disadvantages of current types

a. Tricycle gear
b. High or low wing
c. Helicopters, VTOL aircraft
d. Recognition drills

2. Flying characteristics of various common types

a. Manuals of various aircraft
b. Aircraft operation and limitations
c. Aircraft operation manuals

13969

3. A short history and trends in aircraft development

   a. Improvements in controls and stability
   b. Jet engines for private aircraft

4. The trainer--advantages and disadvantages

   a. Types
   b. Availability in local area

C. Getting up is easy

1. Check list for take-off

2. Take-off procedure

3. Flying speed

   a. Lift in air
   b. Maintaining thrust
   c. Stalls and slips

4. Straight and level flight

   a. Control surfaces
   b. The trim tabs or controls
   c. Slight adjustments--big corrections

D. Landing is a bit more difficult

1. Gliding

   a. Drag
   b. Gravity

2. Momentum

   a. Potential energy
   b. Newton's Laws

3. Effect of winds

4. Round-out, float and touch down

5. Relax slowly

   a. Ground loops
   b. Emergency procedures

13970

13970

E. Caution and knowledge will keep you alive.

1. Weather dangers
2. Aircraft dangers
3. Pilot error

   a. Physiological
   b. Attitudes toward regulations
   c. Alcohol and gas do not mix

4. Regulations to protect the pilot and public

   a. General operating and air traffic rules
   b. Regulation of the student pilot

5. Overview of course stressing <u>reasons</u> for knowing

13971

II. POWER PLANTS

Objectives: (1) To understand reliability of engines
(2) To understand basic thrust
(3) To know advantages and disadvantages of different types of power plants

Methods: Audio-visual aids, films, filmstrips, etc.
Demonstrate model engines, aircraft, auto, other.
Experiments showing combustion, etc.
(Bivisible engines are available at hobby supply shops.)

A. Reciprocating Engine

1. Types of engines

a. Inline
b. V type
c. Fantype (Double V)
d. X type
e. Opposed (flat type)
f. Radial type

1. Single row
2. Double row

2. Engine Parts

a. Cylinder
b. Crankshaft
c. Piston
d. Connecting rod
e. Valves

3. Four cycle principle

a. Intake
b. Compression
c. Power
d. Exhaust

4. Lubrication system

a. Wet-sump
b. Dry-sump

5. Fuels

a. Octane
b. Quality
c. Full systems

13972

OBJECTIVE: To learn how to make and use full sections.

RELATED INFORMATION:

A full section is a part drawn as though cut in half. By this theoretical halving, it is possible to visualize clearly the interior of the part. Drawing the section also eliminates many dashed lines, which often make reading or visualizing very difficult.

FULL SECTION

FIG. 1

VIEW NOT SECTIONED

FIG. 2

Fig. 1 is an example of a full section. Compare this with Fig. 2, which is the same drawing but not sectioned. It can easily be seen which view is clearer. Note the absence of difficult-to-read dashed lines in the sectional view; instead you see solid lines and cross-hatch lines drawn at 45° in opposite directions by the draftsman. These lines aid you to read and visualize much more clearly. Shafts, pins, screws, rivets, and bolts are not cross hatched.

1393 1394

6. Carburetors

   a. Types of carburetors

      1. Float-type
      2. Pressure
      3. Direct injection

   b. Supercharger
   c. Carburetor icing

7. Ignition system

   a. Magneto
   b. Distributor
   c. Spark plug
   d. Two complete ignition systems

      1. Better ignition
      2. Safety factor

8. Cooling system

   a. Liquid cooled
   b. Air cooled
   c. Oil cooled

B. Jets

   1. Newton's Laws
   2. Ramjet
   3. Pulse Jet
   4. Turbojet

      a. Air compressor
      b. Combustion chamber

c. Military application

2. Solid-Propellant rocket

a. Unrestricted burning
b. Restricted burning

3. Liquid-Propellant rocket

a. Monopropellant
b. Bipropellant

4. Nuclear rocket
5. Ion rocket
6. Plasma, photon and water rockets

D. Maintenance and operations of power plants

1. Regulations, FAA
2. Safety Practices (care and feeding of engines)

13974

III. AERODYNAMICS

Objectives: (1) To understand what makes an airplane fly.
(2) To understand that an airplane will fly without power.

Methods: Use dime-store model gliders.
Construct propellers from balsa wood. Use spool, shaft, string and propeller to show lift.

Build models for demonstration.
Build wind tunnel. (Surplus property may be checked for instruments, blowers, etc.)

A. Aerodynamics

1. Subsonic)
2. Transonic) Characteristics
3. Supersonic)

B. Theory of Flight

1. Air as a fluid
2. Lift

   a. Bernouli's Principle (Venturi)

      1. Negative pressure
      2. Positive pressure

   b. Airfoils

      1. Leading edge
      2. Trailing edge
      3. Chord line
      4. Camber

   c. Angle of incidence
   d. Angle of attack

3. Gravity

   a. Center of gravity
   b. Acceleration

4. Thrust

   a. Torque
   b. Propeller - Airfoil

      1. Fixed-pitch
      2. Adjustable-Pitch
      3. Controllable-Pitch

287-386 O - 68 - 2

13975

4. Constant-speed
5. Feathering
6. Reverse thrust

5. Drag

   a. Parasitic
   b. Induced
   c. Streamline

6. Equilibrium

   a. Balance of forces
   b. Forces of inertia

7. Application of theory and controlling an aircraft (attitude)

   a. Pitch
   b. Yaw
   c. Roll
   d. Speed

13970

IV. GENERAL STRUCTURE OF AIRCRAFT

Objectives: (1) To understand how aircraft are built for strength, light weight, and aerodynamic efficiency.

Methods: Films, field trip to maintenance shop, model building

A. Lighter-than-air craft

B. Heavier-than-air craft

1. Wings

a. Method of wing attachment

1. High-wing
2. Low-wing
3. Midwing

b. Structure

1. Aluminum
2. Fabric

c. Secured to airplane

1. Full cantilever
2. Externally braced

d. Ailerons
e. Flaps
f. Rotary wing aircraft

2. Fuselage

a. Aerodynamic shape

1. Providing space for pay load
2. Streamlined

b. Structure

1. Truss - steel tubing
2. Semi-monocoque - metal skin

3. Empennage

a. Horizontal stabilizer

1. Elevator
2. Trim tab

13977

b. Vertical fin

1. Rudder
2. Trim tab

c. Tail rotor system

4. Landing Gear

a. Wheels

1. Conventional
2. Tricycle
3. Bicycle

b. Floats
c. Skis

5. Materials in structures

a. Metals

1. Steel
2. Aluminum
3. Magnesium
4. Titanium

b. Alloys

1. Stainless steel
2. Aluminum alloys
3. Bronze - brass

c. Non-metals

1. Plastics
2. Wood
3. Fibers

6. Regulations governing safety in aircraft structures

13978

V. BASIC FLIGHT INSTRUMENTS

Objectives: (1) To know that certain instruments are required for elementary flight.
(2) To interpret the display presented by the basic flight instruments.

Method: Build an instrument panel.

A. Airspeed indicator

B. Altimeters

1. Indicated altitude
2. True altitude
3. Density altitude
4. Absolute altitude

C. Magnetic compass

1. Compass deviation card

D. Directional gyro

E. Turn and Slip Indicator

1. Ball
2. Turn needle

F. Attitude indicator

G. Electric attitude indicators

H. Clock

I. Vertical velocity indicator

1. Determine rate of climb or descent

13979

VI. AIRPORTS

Objectives: (1) To know the function of the airport and its components
(2) To understand the orderly movement of air traffic on the ground and in flight
(3) To know the services provided at a modern airport

Methods: Build scale-model airport
Use diagrams and scale drawings of various airports
Films

A. Airport Traffic Control

1. Taxiing
2. Landing and Take-off
3. Taxi Patterns

   a. Downwind Leg
   b. Base Leg
   c. Final Approach

4. Light-Signal Procedures

   a. Amber light
   b. White rotating light
   c. Green and white rotating light

B. Air Traffic Control

1. Vertical Separation
2. Longitudinal Separation
3. Lateral Separation
4. Radar Traffic Control
5. IFR Clearances
6. Specified Altitude Clearance

C. Flight Following Function of the ATC Center

1. Position
2. Listening Watch

D. Control of Instrument Approaches

1. Holding
2. Stacking
3. Missed Approaches
4. Approach Control
5. Departure Control

13980

13980

E. Emergency Procedures

1. Radar Assistance

F. Limitations of ATC

G. Services and Organizations

1. Flight operator

2. Federal Aviation Administration

a. Systems Research and Development Service
b. Flight Standards Service
c. Air Traffic Service
d. Airman's Information Manual

3. Civil Aeronautics Board

a. Organization
b. Functions

4. Montana Aeronautics Commission

a. Airport Directory
b. Search and Rescue

H. Federal Aviation Regulations

1. General Operating and Flight Rules - FAR 91
2. General - FAR 91 Subpart A 91.1 - 91.49
3. General Flight Rules - FAR 91 Subpart B - 91.61 - 91.104
4. Visual Flight Rules - FAR 91.105 - 91.109
5. Instrument Flight Rules - FAR 91.115 - 91.129
6. Air Traffic and General Operating Rules - FAR 93
7. Acrobatic Flight - FAR 91.71
8. Takeoff and Landing under IFR - FAR 91.117
9. Operation on and in the vicinity of an airport - FAR 91.85
10. Water operations - FAR 91.69
11. Flight plans - FAR 91.83

I. Field Trip to Airport

1. Layout
2. Services

13981

13985

VII. NAVIGATION

Objectives: (1) To understand principles of cross-country flying
(2) To know basic flight planning procedure
(3) To increase map reading skills

Methods: Use maps, charts, films to demonstrate procedures.

Materials Needed: Charts, maps, protractor, ruler

A. The Globe

1. Introduction, Explanation

a. Our position in space
b. General properties
c. Revolution

1. Seasons
2. The Year

d. Rotation

1. Day and night
2. Time lines

e. The Earth Axis

1. Equinox
2. Solstice

2. The grid system on the globe

a. The great circle
b. Meridian, parallel, longitude, latitude
c. Great circle plotting and the spherimeter

3. Projections

a. Types

1. Cylindrical (mercator)
2. Conic (lambert conformal and polyconic)
3. gnomonic
4. polar

4. Charts, Navigation

a. Geographical
b. Landmark
c. Astrogation (celestial)

13981

13982

ASSIGNMENT:

1. Draw the collar shown below in full section. Draw the centerlines first, then the end view. Project the circles and lay out the lengths of the sectioned view. Place all dimensions as indicated. Draw the cross-hatch lines at a 45° angle. The distance between these lines is approximately $\frac{1}{16}$ inch, spaced by eye. Do not use a mechanical device for spacing lines. Learn to space lines evenly by eye.

COLLAR
FULL SECTION

2. Draw the two views as shown below, with dimensions. Take a full section of the object through the center, as indicated by the heavy cutting-plane line.

1395

d. Radio facilities
e. World
f. Sectional
g. Local
h. Planning
i. Route

B. Pilotage and Dead Reckoning

1. Definition and explanation

a. When and where used
b. Used by whom
c. Limitations

2. The sectional and world chart

a. Identification
b. Marginal information
c. Scale and distance measure
d. Position, latitude and longitude
e. True course line
f. The back of the chart
g. Chart folding
h. Renewal and additional charts
i. Obligations to correct

3. Dead reckoning problems

a. Wind drift
b. Variation
c. Deviation
d. Combining

true course

± wind drift =

true heading

± variation +

magnetic heading

± deviation +

compass heading

e. Ground speed
f. Flight time
g. Fuel rate (and consumption)
h. Planning an alternate airport

13983

4. Planning and Executing a Trip

   a. Find compass heading
   b. Check points
   c. Side and end brackets
   d. Indications of wind

C. Celestial Navigation (optional)

   1. Definition and Explanation

      a. When and where used
      b. Used by whom
      c. Pros and cons

   2. Use of sextant and tables
   3. Theory of "fixing" a position
   4. Methods of "fixing" a position

D. Radio Navigation

   1. Explanation and Definition

      a. When and where used
      b. Used by whom
      3. Pros and cons

(Covered further in Unit X)

13984

VIII. INSTRUMENTS AND SYSTEMS

Objectives: (1) To identify the more sophisticated instruments
(2) To understand the principles of their operations

Methods: Gyroscopes, suction pumps, pitot-static system, demonstrations, drawings and diagrams

A. Pitot-Static and Gyro-Suction Instruments

1. The Pitot-Static source and system
2. The vacuum source and system
3. Pitot-Static instruments

   a. Airspeed indicator

      1. I.A.S.
      2. C.A.S.
      3. T.A.S.

   b. Vertical speed indicator
   c. Altimeter

      1. Reading, setting
      2. Types
      3. Using the altimeter
      4. True altitude
      5. Pressure altitude
      6. Density altitude
      7. Absolute altitude
      8. Temperature correction
      9. Altitude errors

4. Gyro-Suction instruments

   a. The Gyroscope (properties)
   b. The turn and bank indicator

      1. The ball
      2. The turn needle

   c. Gyro-heading indicator

   d. Suction operated horizon indicator

      1. Errors
      2. Caging

13985

13985

B. Electric Instruments

1. Electric source and system
2. Electric turn and bank indicator
3. Electric gyro heading indicator
4. Electric horizon indicator
5. Compass-controlled heading indicator

C. Miscellaneous Instruments

1. Magnetism and magnetic fields
2. Magnetic compass

   a. Variation
   b. Deviation
   c. Magnetic dip
   d. Acceleration error
   e. Oscillation error

3. Engine instruments

   a. tachometer and motor synchronizer

      1. Magneto check

   b. Oil temperature
   c. Oil pressure
   d. Fuel guage
   e. Manifold pressure
   f. Cylinderhead temperature

4. Radar instruments

13985

13986

IX. INSTRUMENT FLYING

Definition: Any flight conducted without visual reference to the ground or horizon.

Objectives: (1) To give the student a basic understanding of the need for instrument flight
(2) To give the student an understanding of how these instruments are interpreted

Suggestions for introducing this unit:
(1) A brief history of the unexplained crashes of the early days
(2) Discussion of such terms as:
(a) Flying by the seat of the pants (deep sensations of the viscera)
(b) Graveyard spiral
(3) An explanation of the nature of the inner ear and how it functions
(a) Reasons for vertigo
(b) Need for disregarding sensations of vertigo when they conflict with instrument readings

Materials needed: Radio facilities, charts, plotters, computers

A. Attitude instrument flight, controls

Definition of Attitude: The relationship of the longitudinal axis and the lateral axis to the earth's surface or any plane parallel to the earth's surface.

1. Using the throttle to control altitude
2. Using the elevators to control the pitch
3. Bank control
4. Trim control

B. Fundamental aircraft accessories related to instrument flight

1. Pitot static tube
2. Venturi tube
3. Electrical system
4. Anti-icing equipment

C. Gyroscope, interpretation of

1. Momentum and its resistance to change of direction
2. Precession and its application to flight instruments
3. Drift and its relation to instrument error

13987

4. Methods of maintaining rotation of the gyroscope

   a. Electric
   b. Vacuum

      1. Venturi
      2. Engine driven pump

D. Interpretation of Flight Instrument Readings

   1. Sensitive altimeter
   2. Vertical speed indicator (rate of climb indicator)
   3. Turn and bank (rate of turn indicator)
   4. Horizon indicator (artificial horizon, gyro-horizon)
   5. Airspeed indicator
   6. Heading indicator (gyro-compass)
   7. Magnetic compass

E. Maintaining attitude by instruments

   1. Instrument coverage techniques (scanning)
   2. Instrument interpretation
   3. Aircraft control

F. Radio facilities available to the instrument pilot

   1. Radio facilities charts, Jeppeson and U. S. Coast

G. FAA Regulations pertaining to instrument flight

   1. Requirements
   2. Maintaining proficiency

13988

X. METEOROLOGY AND WEATHER

Objectives: (1) To enable students to obtain and interpret weather data
(2) To recognize severe or dangerous conditions

Methods: Field trip to weather bureau
Build observation station
Films

A. Much current weather data is available

1. Visit a weather bureau station
2. Teletype circuits
3. Facsimile transmissions
4. Weather satellite photos

B. Making weather observations

1. Sky conditions and visibility
2. Temperature and dew point
3. Atmospheric pressure and changes
4. Wind direction and velocity
5. Radar weather

C. Analysis of data

1. Weather maps
2. Upper air analysis
3. Winds aloft charts

D. Air mass theory

1. Types and source regions
2. Characteristic weather phenomena
3. Air and pressure pattern movements
4. Relationship of air mass to surface

E. Fronts and severe weather

1. Cold fronts
2. Warm fronts
3. Occlusions
4. Effects on aircraft

F. Local topographical effects

1. Upslope fog and weather
2. Mountain weather
3. Elevation, temperature and air density

13989

G. Preparing forecasts

1. Projecting weather patterns
2. Anticipating characteristic weather
3. Diurnal effects

H. Interpreting and evaluating weather reports and forecasts

1. Symbols and abbreviations
2. Recognizing dangerous conditions
3. Effects of winds and weather on flight plans
4. Obtaining and using weather information in flight

I. Federal Regulations applicable

13990

13983

XI. RADIO COMMUNICATIONS AND RADIO NAVIGATION

Objectives:
(1) To acquaint the student with services available to airplanes with radio equipment
(2) To give the student an understanding of how to use the radio for navigation
(3) To give the student an understanding of how to transmit and receive voice on a radio set
(4) To acquaint the student with Federal Air Regulations pertaining to the use of two-way radio by pilots

Suggestions for introducing this unit:
(1) Discuss advantages and safeties provided by radio in connection with airplane flight
IFR - Simplified Navigation
VFR - Traffic control, weather and airport information, emergencies
(2) The nature of radio waves and natural laws which affect them (Doppler effect)
Line of sight transmission, interference, frequencies
(3) A comparison of low frequencies and high frequencies (disadvantages and advantages) or <u>adaptability</u>
(4) Memorize the frequencies ranges

A. Using a radio set for communication

1. Verbal skills required

a. Phonetic alphabet
b. Numbers and their pronunciation
c. Phraseology and its purpose
d. Courtesies of use
e. Types of messages and the methods used in each

2. Situations

a. Taxiing and take-off
b. Landing
c. In flight

1. PIREPS
2. Unicom
3. Weather

d. Emergency

B. Using Radio for Navigation

1. Low frequencies and radio range
2. Medium frequencies and the A.D.F.

13991

13991

3. VHF (Omnirange [VOR] Stations)

   a. The nature of the station and the signal sent
   b. The receiver and its facilities
   c. Skills required

      1. Using chart and map information
      2. Use of To-From indicator
      3. Use of the radial or bearing selector
      4. Flying a radial
      5. Intercepting a radial
      6. Fixing a position
         Without DME
         With DME

4. Other radio navigation facilities

   a. ILS facilities
   b. Marker beacons
   c. Radar

C. Services available to pilots using two-way radio

   1. ATC
   2. FSS
   3. FI Watch
   4. Emergency homing
   5. Victor airways

D. Aids to radio navigation

   1. Maps
   2. Radio
   3. Charts
   4. Flight information manual

E. Federal Communications Commission regulations

   1. The Aircraft
   2. The Pilot

13991

13992

3. Draw the two views as shown below, with dimensions. Take a full section of the object through the center, as indicated by the heavy cutting-plane line.

1398

XII. FLIGHT PLANNING

Objectives: (1) To use acquired skills in planning a flight
(2) To demonstrate organization and use of information

Methods: Plan an actual or simulated cross-country flight
Each student plan flight and keep log

Materials: Maps, charts, plotter, computer, weather data, flight information manuals

A. Flight Plan

1. File
2. Close
3. Enroute change
4. Enroute report

B. Dead reckoning

1. Computer
2. Clock

C. Map reading

1. Airport directories
2. Jeppeson charts
3. Maps

D. Aircraft characteristics

1. Cruising altitude
2. Oxygen or pressurization
3. Distance of flight as compared to fuel range of airplane
4. Navigation equipment
5. Owner's manual

E. Weather

F. Route

G. Fuel requirements

H. Position determination

I. Airways Flying

J. Regulations

1. Violations of regulations
2. Accident report

13993

XIII. REVIEW FOR EXAM

A. Theory of Flight

B. Aircraft Instruments and Instrument Flying

C. Basic Flight Techniques

D. Weather

E. Navigation

F. Flight Control Agencies

G. Aircraft Maintenance

H. Regulations

13994 13997

XIV. CAREERS AND VOCATIONAL OPPORTUNITIES (Optional)

This unit may be used directly after Unit XI, or at any time the teacher desires. Its purpose is to survey the wide range of vocational opportunities in the field of aviation.

A. Outline of the aerospace industry

1. Aerospace manufacturing industry

   a. Aircraft
   b. Aircraft engines
   c. Aircraft parts and accessories
   d. Missiles
   e. Spacecraft

2. Air transport industry

   a. Domestic scheduled airline

      1. Trunk lines
      2. Local service lines
      3. Helicopter airlines
      4. Supplemental carriers

   b. International and overseas airlines
   c. Alaskan carriers
   d. Intra-Hawaiian carriers
   e. All-cargo carriers

3. General aviation

   a. Business flying
   b. Commercial flying
   c. Instructional flying
   d. Personal flying

B. Types of jobs

1. Airline operations
2. Aircraft manufacturing
3. Agricultural operations
4. Aviation in government (non-military)
5. Military aviation

C. Employment outlook

1. Professional and semi-professional
2. Skilled
3. Semi-skilled
4. Unskilled

13995

D. Choosing a career in aviation

1. Needs of industry (present and anticipated)
2. Age and background
3. Interests and aptitudes
4. Wages and working conditions
5. Hours and advancement
6. Where the employment is
7. Nature of a union
8. Labor-management relationship

E. How this course can help you as a student

1. Contact with needs and opportunities
2. Early evaluation of personal interests and aptitudes
3. Broad knowledge of the whole field helpful
4. Specific knowledge of piloting techniques

13996

Reprinted from:
AIM-May 1967

APPENDIX 1

Chapter 1—BASIC FLIGHT MANUAL

GLOSSARY OF AERONAUTICAL TERMS

ADVISORY SERVICE—Advice and information provided by a facility to assist pilots in the safe conduct of flight and aircraft movement.

AIR DEFENSE IDENTIFICATION ZONE (ADIZ)—The area of airspace over land or water within which the ready identification, the location, and the control of aircraft are required in the interest of national security. For operating details see ADIZ procedures.

AIRPORT ADVISORY AREA—The area within five statute miles of an uncontrolled airport on which is located a Flight Service Station so depicted on the appropriate Sectional Aeronautical Chart.

AIRPORT ADVISORY SERVICE—A service provided by a Flight Service Station to enhance the safety of terminal operations of airports where a station is operating but where there is no control tower.

AIRPORT INFORMATION DESK (AID)—A local airport unmanned facility designed for pilot self-service briefing, flight planning and filing of flight plans.

AIRPORT SURFACE DETECTION EQUIPMENT (ASDE)—Radar equipment specifically designed to detect all principal features on the surface of an airport, including vehicular traffic, and to present the entire picture on a radar indicator console in the control tower. ASDE has a maximum range of four miles, though its 16 inch diameter scope usually displays an area of only one mile radius about the control tower.

AIRPORT SURVEILLANCE RADAR (ASR)—Radar providing position of aircraft by azimuth and range data without elevation data. It is designed for a range of 50 miles.

AIRPORT TRAFFIC AREA—Unless otherwise specifically designated (FAR Part 93), that airspace with a horizontal radius of five statute miles from the geographical center of any airport at which a control tower is operating, extending from the surface up to, but not including, 2,000 feet above the surface.

AIR ROUTE SURVEILLANCE RADAR (ARSR)—Long range radar which increases the capability of ATC for handling heavy en route traffic. An ARSR site is usually located at some distance from the ARTCC it serves.

AIR ROUTE TRAFFIC CONTROL CENTER (CENTER)—A facility established to provide air traffc control service to aircraft operating on an IFR flight plan within controlled airspace and principally during the en route phase of flight.

AIR TRAFFIC—Aircraft operating in the air or on an airport surface, exclusive of loading ramps and parking areas.

AIR TRAFFIC CLEARANCE (CLEARANCE)—An authorization by air traffic control for the purpose of preventing collision between known aircraft, for an aircraft to proceed under specified traffic conditions within controlled airspace.

AIR TRAFFIC CONTROL SERVICE (CONTROL)—A service provided for the purpose of promoting the safe, orderly, and expeditious flow of air traffic, including airport, approach, and enroute air traffic control service.

ALTITUDE RESERVATION (ALTRV)—Airspace utilization under prescribed conditions, normally employed for the mass movement of aircraft or other special user requirements which cannot otherwise be accomplished. ALTRV's are approved by the appropriate FAA facility.

APPROACH CONTROL SERVICE—Air traffic control service, provided by a terminal area traffic control facility, for arriving and departing IFR aircraft and, on occasion, VFR aircraft.

APPROACH FIX—The fix from or over which final approach (IFR) to an airport is executed.

APPROACH SEQUENCE—The order in which aircraft are positioned while awaiting approach clearance or while on approach.

AUTOMATIC TERMINAL INFORMATION SERVICE (ATIS)—The continuous broadcast of recorded noncontrol information in selected high activity terminal areas. Its purpose is to improve controller effectiveness and to relieve frequency congestion by automating the repetitive transmission of essential but routine information.

CARDINAL ALTITUDES OR FLIGHT LEVELS—"Odd" or "even" thousand-foot altitudes or flight levels. Examples: 5000, 6000, 7000, FL 250, FL 260, FL 270.

CAUTION AREA—Airspace within which military activities are conducted that are not hazardous but are of interest to nonparticipating pilots.

CEILING—The height above the earth's surface of the lowest layer of clouds or obscuring phenomena that is reported as "broken," "overcast," or "obscuration" and not classified as "thin" or "partial."

CENTRAL ALTITUDE RESERVATION FACILITY (CARF)—An Air Traffic Service facility established to conduct the volume of coordination, planning and approval of special user requirements under the altitude reservation concept.

CLEARANCE LIMIT—The fix to which an aircraft is issued an air traffic clearance.

CODES—The numbers assigned to the multiple pulse reply signals transmitted by ATCRBS and SIF transponders.

CONSOLAN—A low frequency, long-distance navaid used principally for transoceanic navigation.

CONTACT APPROACH—An approach wherein an aircraft on an IFR flight plan, operating clear of clouds with at least one mile flight visibility and having received an

13997

GLOSSARY OF AERONAUTICAL TERMS

air traffic control authorization, may deviate from the prescribed instrument approach procedure and proceed to the airport of destination by visual reference to the surface.

CONTERMINOUS U.S.—Forty-eight states and the District of Columbia.

CONTINENTAL U.S.—Forty-nine states. The original 48 states and Alaska.

CONTROLLED AIRSPACE—Airspace designated as continental control area, control area, control zone, or transition area, within which some or all aircraft may be subject to air traffic control.

Continental control area—Airspace at and above 14,500 feet MSL of the 48 contiguous states, the District of Columbia, and Alaska south of Lat. 68°00′00″N, excluding the Alaska peninsula west of Long. 160°-00′00″W; but does not include airspace less than 1,500 feet above the surface of the earth, and prohibited and restricted areas (except certain specified restricted areas).

Control area—Unless otherwise specified, airspace extending upward from 700 feet above the surface of the earth (until designated from 1,200 feet or more).

Control zone—Airspace extending upward from the surface of the earth which may include one or more airports and is normally a circular area of five statute miles in radius with extensions where necessary to include instrument approach and departure paths.

Transition area—Airspace extending upward from 700 feet or more above the surface of the earth when designated in conjunction with an airport for which an approved instrument approach procedure has been prescribed, or from 1,200 feet or more above the surface of the earth when designated in conjunction with airway route structures or segments. Unless otherwise limited, transition areas terminate at the base of the overlying controlled airspace.

COURSE—The intended direction of flight in the horizontal plane. Also a leg of an L/MF range.

CRUISE—A word used instead of the word "maintain" in an ATC clearance to indicate to a pilot that climb to and descent from the assigned altitude may be made at his discretion.

CRUISING ALTITUDE—A level determined by vertical measurement from mean sea level.

DEPARTURE CONTROL—A function of approach control providing service for departing IFR aircraft and on occasion, VFR aircraft.

DISCRETE FREQUENCY—A frequency assigned a particular function.

DISTANCE MEASURING EQUIPMENT (DME)—Equipment (airborne and ground) used to measure, in nautical miles, the distance of an aircraft from a navaid.

DME FIX—A geographical position determined by reference to a navaid which provides distance and azimuth information and defined by a specified distance in nautical miles and a radial in degrees magnetic from that aid.

DME SEPARATION—Spacing of aircraft in terms of distance determined by reference to distance measuring equipment (DME).

EN ROUTE AIR TRAFFIC CONTROL SERVICE—Air traffic control service provided aircraft on an IFR flight plan, generally by centers, when these aircraft are operating between departure and destination terminal areas.

EXPECTED APPROACH CLEARANCE TIME (EAC)—The time at which it is expected that an arriving aircraft will be cleared to begin approach for a landing.

EXPECTED FURTHER CLEARANCE TIME (EFC)—The time at which it is expected that additional clearance will be issued to an aircraft.

FINAL APPROACH—IFR—The flight path of an aircraft which is inbound to the airport on an approved final instrument approach course, beginning at the point of interception of that course and extending to the airport or the point where circling for landing or missed approach is executed.

FINAL APPROACH—VFR—A flight path of a landing aircraft in the direction of landing along the extended runway centerline from the base leg to the runway.

FINAL CONTROLLER—That controller providing final approach guidance utilizing precision approach radar equipment.

FIX—A geographical position determined by visual reference to the surface by reference to one or more radio navaids, by celestial plotting, or by another navigational device.

FLIGHT LEVEL (FL)—A level of constant atmospheric pressure related to a reference datum of 29.92 inches of mercury. Each is stated in three digits that represent hundreds of feet. For example, FL 250 represents a barometric altimeter indication of 25,000 feet. FL 255 indicates 25,500 feet.

FLIGHT PLAN—Specified information relating to the intended flight of an aircraft that is filed orally or in writing with an air traffic control facility.

FLIGHT SERVICE STATION (FSS)—A facility operated by the FAA to provide flight assistance service.

FLIGHT VISIBILITY—The average forward horizontal distance from the cockpit of an aircraft in flight at which prominent unlighted objects may be seen and identified by day and prominent lighted objects may be seen and identified by night.

FLIP—Flight Information Publication.

GROUND VISIBILITY—Prevailing horizontal visibility near the earth's surface as reported by the U.S. Weather Bureau or an accredited observer.

HERTZ (Hz)—Cycle or cycles per second.

HOLDING—A predetermined maneuver which keeps an aircraft within a specified airspace while awaiting further clearance.

HOLDING FIX—A specified fix used as a reference point in establishing and maintaining the position of an aircraft while holding.

"IDENT" FEATURE—The special feature in ATCRBS equipment and the "I/P" feature in certain SIF equipment used to distinguish one displayed select code from other codes.

IFR CONDITIONS—Weather conditions below the minimum prescribed for flight under VFR.

INTENSIVE STUDENT JET TRAINING AREA—Airspace which contains the intensive training activities of military student jet pilots and in which restrictions are imposed on IFR flight.

INTERROGATOR—The ground-based surveillance radar beacon transmitter-receiver which scans in synchronism with a primary radar, transmitting discrete radio signals

13998

13998

GLOSSARY OF AERONAUTICAL TERMS

which repetitiously request all transponders, on the mode being used, to reply. The replies received are then mixed with the primary radar video to be displayed on the same plan position indicators. **"I/P" FEATURE**—(See "IDENT" feature.)

JET ADVISORY SERVICE—The service provided certain civil aircraft while operating within radar and nonradar jet advisory areas. Within radar jet advisory areas, civil aircraft receiving this service are provided radar flight following, radar traffic information, and vectors around observed traffic. In nonradar jet advisory areas, civil aircraft receiving this service are afforded standard IFR separation from all other aircraft known to ATC to be operating within these areas.

JET ROUTES—A high altitude route system, at the above 18,000 feet MSL, predicated on a network of designated high altitude VHF/UHF facilities. (For operating procedures applicable to this system see EN ROUTE).

JOINT USE RESTRICTED AREA—A restricted area within which IFR and/or VFR flight operations may be authorized by the controlling agency (a FAA facility) when not in use by the using agency.

MAXIMUM AUTHORIZED ALTITUDE (MAA)—The highest altitude on a Federal airway, jet route, or other direct route for which a MEA is designated in F.A.R. Part 95 at which adequate reception of navigation aid signals is assured.

MINIMUM CROSSING ALTITUDES (MCA)—The lowest altitudes at certain radio fixes at which an aircraft must cross when proceeding in the direction of a higher minimum en route IFR altitude.

MINIMUM EN ROUTE IFR ALTITUDE (MEA)—The altitude in effect between radio fixes which assures acceptable navigational signal coverage and meets obstruction clearance requirements between those fixes.

MINIMUM OBSTRUCTION CLEARANCE ALTITUDE (MOCA)—The specified altitude in effect between radio fixes on VOR/LF airways, off-airway routes on route segments, which meets obstruction clearance requirements for the entire route segment and which assures acceptable navigational signal coverage only within 22 nautical miles of a VOR.

MINIMUM RECEPTION ALTITUDE (MRA)—The lowest altitude required to receive adequate signals to determine specific VOR/VORTAC/TACAN fixes.

MODE—The number or letter referring to the specific pulse spacing of the signal transmitted by an interrogator.

MOVEMENT AREA—The runways, taxiways, and other areas of an airport which are used for taxiing, takeoff, and landing of aircraft, exclusive of loading ramps and parking areas.

NOTICE TO AIRMEN—A notice identified either as a NOTAM or Airmen Advisory containing information concerning the establishment, condition, or change in any component of, or hazard in, the National Airspace System, the timely knowledge of which is essential to personnel concerned with flight operations.

(1) *NOTAM.* A Notice to Airmen in message form requiring expeditious and wide dissemination by telecommunications means.

(2) *Airmen Advisory.* A Notice to Airmen normally only given local dissemination, during preflight or in-flight briefing, or otherwise during contact with pilots.

OUTER FIX—A fix in the destination terminal area, other than the approach fix, to which aircraft are normally cleared by an air route traffic control center or a terminal area traffic control facility, and from which aircraft are cleared to the approach fix or final approach course.

PRECISION APPROACH—An instrument approach conducted in accordance with directions issued by a controller referring to the surveillance radar display until the aircraft is turned onto final approach and, thereafter, to a precision approach radar display.

PROHIBITED AREA—Airspace of defined dimensions identified by an area on the surface of the earth within which flight is prohibited.

RADAR (RADIO DETECTION AND RANGING)—A device which, by measuring the time interval between transmission and reception of radio pulses and correlating the angular orientation of the radiated antenna beam or beams in azimuth and/or elevation, provides information on range, azimuth and/or elevation of objects in the path of the transmitted pulses.

Radar beacon (secondary radar)—A radar system in which the object to be detected is fitted with cooperative equipment in the form of a radio receiver/transmitter (transponder). Radio pulses transmitted from the searching transmitter/receiver (interrogator) site are received in the cooperative equipment and used to trigger a distinctive transmission from the transponder. This latter transmission rather than a reflected signal, is then received back at the transmitter/receiver site.

RADAR ADVISORY—The term used to indicate that the provision of advice and information is based on radar observation. (See Advisory Service)

RADAR CONTACT—The term air traffic controllers use to indicate that an aircraft is identified on the radar display and that radar service can be provided until radar identification is lost or radar service is terminated, and that when the aircraft is informed of "radar contact" it automatically discontinues reporting over compulsory reporting points.

RADAR FLIGHT FOLLOWING—The radar tracking of identified aircraft targets and the observation of the progress of such flights sufficiently to retain identity.

RADAR HANDOFF—That action whereby radar identification of, radio communications with and, unless otherwise specified, control responsibility for an aircraft is transferred from one controller to another without interruption of radar flight following.

RADAR IDENTIFICATION—The process of ascertaining that a radar target is the radar return from a particular aircraft.

RADAR SERVICE—A term which encompasses one or more of the following services based on the use of radar which can be provided by a controller to a pilot of a radar-identified aircraft.

Radar Separation—Radar spacing of aircraft in accordance with established minima.

Radar Navigation Guidance—Vectoring aircraft to provide course guidance.

Radar Monitoring—The radar flight following of aircraft, whose primary navigation is being performed by the pilot, to observe and note deviations from its

GLOSSARY OF AERONAUTICAL TERMS

authorized flight path airway, or route. This includes noting aircraft position relative to approach fixes and major obstructions.

RADAR SURVEILLANCE—The radar observation of a given geographical area for the purpose of performing some radar function.

RADAR VECTOR—A heading issued to an aircraft to provide navigational guidance by radar.

RADIAL—A radial is a magnetic bearing extending from a VOR, VORTAC, or TACAN.

REPORTING POINT—A geographical location in relation to which the position of an aircraft is reported.

RESTRICTED AREA—Airspace of defined dimensions identified by an area on the surface of the earth within which the flight of aircraft, while not wholly prohibited, is subject to restrictions.

ROUTE—A defined path, consisting of one or more courses, which an aircraft traverses in a horizontal plane over the surface of the earth. (See JET ROUTES)

SELECT CODE—That code displayed when the ground interrogator and the airborne transponder are operating on the same mode and code simultaneously.

SEPARATION—Spacing of aircraft to achieve their safe and orderly movement in flight and while landing and taking off.

SEPARATION MINIMA—The minimum longitudinal, lateral, or vertical distances by which aircraft are spaced through the application of air traffic control procedures.

SPECIAL VFR CONDITIONS (SPECIAL VFR MINIMUM WEATHER CONDITIONS)—Weather conditions which are less than basic VFR weather conditions and which permit flight under Visual Flight Rules.

SPECIAL VFR OPERATIONS—Aircraft operating in accordance with clearances within control zones in weather conditions less than the basic VFR weather minima.

STRAIGHT-IN APPROACH—IFR—An instrument approach wherein final approach is begun without first having executed procedure turn.

STRAIGHT-IN APPROACH—VFR—Entry of the traffic pattern by interception of the extended runway centerline without executing any other portion of the traffic pattern.

SURVEILLANCE APPROACH—An instrument approach conducted in accordance with directions issued by a controller referring to the surveillance radar display.

TRACK—The flight path of an aircraft over the surface of the earth.

TRAFFIC INFORMATION–RADAR—Information issued to alert an aircraft to any radar targets observed on the radar display which may be in such proximity to its position or intended route of flight to warrant its attention.

TRAFFIC PATTERN—The traffic flow that is prescribed for aircraft landing at, taxiing on, and taking off from an airport. The usual components of a traffic pattern are upwind leg, crosswind leg, downwind leg, base leg, and final approach.

TRANSPONDER—The airborne radar beacon receiver-transmitter which automatically receives radio signals from all interrogators on the ground, and which selectively replies with a specific reply pulse or pulse group only to those interrogations being received on the mode to which it is set to respond.

VFR CONDITIONS—Basic weather conditions prescribed for flight under Visual Flight Rules.

VISIBILITY, PREVAILING—The horizontal distance at which targets of known distance are visible over at least half of the horizon. It is normally determined by an observer on or close to the ground viewing buildings or other similar objects during the day and ordinary city lights at night. Under low visibility conditions the observations are usually made at the control tower. Visibility is REPORTED IN MILES AND FRACTIONS OF MILES in the Aviation Weather Report. If a single value does not adequately describe the visibility, additional information is reported in the "Remarks" section of the report.

VISIBILITY, RUNWAY—The horizontal distance at which a stationary observer near the end of the runway can see an ordinary light (about 25 candlepower) at night or a dark object against the horizon sky in the daytime. In practice the human observer is used very little for this observation. Instead runway visibility is normally determined by a transmissometer (a photoelectric device calibrated in terms of a human observer). It is REPORTED IN MILES AND FRACTIONS OF MILES in the "Remarks" section of the Aviation Weather Report. A meter in the control tower gives the FAA traffic controller a continuous indication of the runway visibility at transmissometer locations. Runway visibility, where available, is used in place of prevailing visibility for the determination of minimums on a transmissometer runway. This program is gradually being replaced by Runway Visual Range at transmissometer locations.

VISIBILITY, RUNWAY VISUAL RANGE (RVR)—An instrumentally derived value, based on standard calibrations, that represents the horizontal distance a pilot will see down the runway from the approach end; it is based on the sighting of either high intensity runway lights or on the visual contrast of other targets—whichever yields the greater visual range. RVR, in contrast to prevailing or runway visibility, is based on what a pilot in a moving aircraft should see looking down the runway. RVR is horizontal, AND NOT SLANT, visual range. It is based on the measurement of a transmissometer made near the touchdown point of the instrument runway and is REPORTED IN HUNDREDS OF FEET. At the present time, RVR observations are automatically furnished to FAA tower controllers at approximately 25 locations from readout equipment connected to the remote transmissometer installation. RVR provides an additional operating minimum at fields equipped with specified navigational aids. For example, at the present time the RVR minimum at Newark is 2000 ft. (in combination with a minimum descent altitude of 218′ MSL) for both takeoffs and landings regardless of the reported ceiling and visibility.

VISUAL APPROACH—An approach wherein an aircraft on an IFR flight plan, operating in VFR conditions and having received an air traffic control authorization, may deviate from the prescribed instrument approach procedures and proceed to the airport of destination by visual reference to the surface.

VOT (VERY HIGH FREQUENCY OMNITEST)—A ground originating test signal used to check the accurate alignment of a VOR receiver.

WARNING AREA—Airspace which may contain hazards to nonparticipating aircraft in international airspace.

OBJECTIVE: To learn how to make and use half sections.

VIEW NOT SECTIONED (a)

HALF SECTION (b)

FIG. 1

RELATED INFORMATION:

Not all drawings require full sections. Many times it is preferable to draw a half section, so that a single drawing can show part of the outside and part of the inside. Note the pulleys shown in Fig. 1. See how the pulley not shown in section (View a) is so much more difficult to read.

ASSIGNMENT:

The front and right-side view of a collar are shown below. Draw the front view as shown but change the right-side view to a half section. Dimension fully.

UNIT I - INTRODUCTION

ACHIEVEMENT TEST

QUESTIONS:

1. What professions use drafting?
2. Why is drafting important?
3. Give a practical application of drafting.
4. Can an individual who is sloppy by nature hope to be a successful draftsman?
5. In your own words, briefly explain orthographic projection.
6. Why is lettering considered important?
7. Explain the use of guide lines.

PROBLEMS:

On the $8\frac{1}{2}$ x 11 inch buff paper issued to you, draw horizontal guide lines $\frac{1}{8}$ inch apart across the paper, allowing $\frac{1}{4}$ inch between each pair of lines.
Letter the following:

a. Any three sentences.

b. Bill of materials.

PREFACE

The first edition of HEALTH CAREERS BIBLIOGRAPHY FOR GUIDANCE COUNSELORS that was published in 1964 by the New Jersey Health Careers Service proved to be a very valuable and effective reference tool for guidance counselors and others charged with the responsibility of helping young people with their career planning and vocational decisions. That the BIBLIOGRAPHY filled a basic need is indicated by its extensive use as a quick and easy guide to health career information; and by numerous requests for current, supplementary data pertaining to the expanding and newly developing job opportunities in the health field.

Disseminating occupational information carries with it responsibility for keeping it accurate, recent, comprehensive, and available. Busy counselors find it difficult to keep pace with the increasing output of publications on health careers that appear in many printed forms with varying degrees of quality and usefulness. They seek and welcome authoritative sources of such data.

In response to requests for up-to-date and authentic resources covering the increasing and changing occupational opportunities within the health manpower area, the New Jersey Health Careers Service provided a grant for a special project to revise, expand, and update the first edition of HEALTH CAREERS BIBLIOGRAPHY. This second edition supplements the first effort, listing only those materials published since 1964 to the present. References can still be made to the first edition for earlier publications.

The arduous task of gathering, reviewing and evaluating quantities of printed materials that describe health occupations was undertaken by Peter Fabriele, a guidance counselor with an M.A. in Student and Personnel Services. Appreciation is extended to him for endless hours of research to produce this BIBLIOGRAPHY. Over 3500 items were examined of which 1500 were selected for inclusion in this edition, based upon evaluation standards of NVGA criteria.

This HEALTH CAREERS BIBLIOGRAPHY is unique in that it brings together in a single publication such a large body of references on such a large spread of occupations in the health field. It is hoped that further revisions and supplements can be made from time to time to keep it accurate and up-to-date so that it can continue to serve as a

0S0A1

14021

valuable resource aid for presenting occupational information to young people interested in pursuing careers in health.

The New Jersey Health Careers Service is a state-wide voluntary organization made up of different professional associations in the State representing health and educational groups, civic and community organizations who share a common interest in helping to motivate interest of young people in health careers. This BIBLIOGRAPHY and other aids such as a quarterly Newsletter, films and audio visual materials, speakers, etc., are available upon request from the New Jersey Health Careers Service, 375 West State Street, Trenton New Jersey 08618, (609-695-9445).

Carrie R. Losi, Consultant

UNIT II - USE OF DRAWING INSTRUMENTS

ACHIEVEMENT TEST

On the sheet of paper issued to you, write the word or phrase (found in the parentheses below) that best completes the following questions or statements.

1. The main function of a T-square is to guide a pencil when drawing (vertical, parallel, horizontal)lines.

2. The best method for cleaning a T-square is to use (water, crumpled paper, eraser, good cleaning fluid).

3. Drawings made on white or buff drawing paper cannot be (traced, erased, blueprinted).

4. The best method for fastening drawing paper to a board is to use (thumbtacks, Scotch drafting tape, staples, rubber cement).

5. The most useful pencil for drawing guide lines is (soft, hard, medium).

6. The most useful pencil for sketching freehand is (soft, hard, medium).

7. The most commonly used triangles are the (30°, 40°, 45°, 60°, 70°, 80°).

8. The main function of the triangles is to guide a pencil when drawing (vertical, parallel, horizontal) lines.

9. There are numerous scales to choose from, but for our purposes we shall use the (mechanical engineer's, carpenter's, architect's, plumber's) scale.

10. A bow compass is used for (drawing circles, measuring angles).

11. A protractor is used to (draw circles, measure angles, mark off distances).

12. If a particular problem on a protractor requires a measurement between a half degree and a full degree, it must be (estimated, computed, use a scale).

NATIONAL BUREAU OF STANDARDS-1963-A

INTRODUCTION

The overwhelming task of gleaning from currently published occupational literature those items which meet professional standards of accuracy, reliability, and currency is indeed a formidable one. Under several occupational headings, the counselor finds a dearth of materials, under others there is an excess. Some materials approach a high degree of accuracy and reliability, others are less desirable and often misleading, and provide little, if any, value.

The first edition of Health Careers Bibliography for Guidance Counselors published in 1964 by the New Jersey Health Careers Service analyzed the bulk of extant occupational literature from this maze of data and compiled a classified, alphabetical listing of health careers publications that were screened and evaluated according to National Vocational Guidance Association (NVGA) Standards for Use in Preparing and Evaluating Occupational Literature. The Bibliography proved to be a very valuable and useful tool for counselors who were responsible for helping students with their career planning.

The thrust of this revised Bibliography was to supplement the earlier effort by investigation of newly published materials, rather than to repeat inclusion of items that already appear in the first edition. Accordingly, materials reviewed for the second edition represent those published since 1964 up to the present. Materials for this revised edition were assembled from more than 400 sources including: publishers, professional organizations, federal and state agencies, hospitals, schools, and industries. Over 3,000 health career brochures, pamphlets, monographs, fact sheets, abstracts, job series, briefs, books, etc., were reviewed and evaluated, using the NVGA Standards as a basis for selection. Included are the medical careers and the related careers that are necessary in the coordination and maintaining of essential health services. Several new careers have been added, such as areas of aerospace medicine, computer operator, counselor, and others. There is represented a wide range of occupations requiring differing levels of education, training, intellectual abilities, skills and responsibilities that are found in the many different work settings and types of activities in health careers.

After careful research and evaluation, those items deemed appropriate were classified alphabetically according to the health career designations and code numbers of the Dictionary of Occupational Titles (DOT). This classification and coding system enhances the effectiveness of the Bibliography for counseling purposes. It simplifies the filing and

14023

retrieving of occupational data. Also, at the end of each item, letters from A to N refer to the type of publication; and the numbers 1, 2, and 3 refer to the kind of recommendation, whether it is highly recommended, recommended, or useful, as presented in the NVGA Classification and Coding Guide on the following page.

Expenditures necessary to purchase the various items listed in the Bibliography vary. Many of the paperback materials, pamphlets, booklets, and fact sheets are relatively inexpensive; in many instances they are free. Hard cover materials or books of biography and other non-fiction, cost considerably more, within a wide price range. Selection of books was necessarily limited. Only those books which would have motivational value for counseling young people were chosen. Selections were further limited, since the output of suitable career books during the years 1965-69 was not extensive. References to books published prior to 1965 can be made to the first edition of the Bibliography.

Gratitude is extended to the many groups and organizations who have contributed materials and information that made this publication possible. It is hoped that counselors will find this revision and updating of the Health Careers Bibliography a valuable resource aid.

14024

CLASSIFICATION AND CODING GUIDE *

	Type of Publication
A-Career Fiction	An account, portrayed through the experiences of one or more fictional characters, of an occupation which may encompass duties, qualifications, preparations, conditions, and nature of work and advancement.
B-Biography	An account of the life of a successful man or woman in a given field of endeavor portraying the problems faced by these people in preparing for an advancement in their careers.
C-Occupational Monograph	Extensive coverage of all phases of an occupation. A detailed, comprehensive analysis of a field of work and its related occupations. (about 4,000 - 8,000 words)
D-Occupational Brief	Covers the various types of specialization in an occupational field in general terms. Not as extensive as a monograph, yet describes all phases of the various job opportunities. Usually prose style. (about 3,000 words)
E-Occupational Abstract	A concise summary of a job in an occupational area citing the duties and nature of employment, etc., in general terms. May be in prose or outline form. (about 1,500 words)
F-Occupational Guide	Brief facts about various phases of an occupational title. Contains general information about the occupation but does not describe any particular job. May be in outline form. Often a booklet or leaflet.
G-Job Series	Broad coverage of an entire occupational area giving brief accounts of all job opportunities in the field. May be book, manual, or article.
H-Business and Industrial descriptive literature	Describes a particular business or industry. May show scope and pattern of occupational opportunities.

* NVGA Bibliography of Current Occupational Literature 1966 Edition, Career Information Review Service of the National Vocational Guidance Association, APGA, Washington, D. C.

14025

I-Occupational or industrial description	Describes the principal opportunities of an occupation in one industry or one occupation in several industries. Discusses an occupation as it relates to employment opportunities in industry. May include a brief account of the industry or industries.
J-Recruitment literature	Descriptive promotional information pointed toward recruiting young men and women in an occupation or career field. Brief coverage of facts.
K-Poster or Chart	Occupational information presented by pictures, graphs, tables, etc., in black and white or color, portraying information about jobs, opportunities, trends, qualifications and preparation. Data in concise summarized form permitting a quick review of, or stimulating an interest in, a major occupational group.
L-Article or reprint	An account of an occupation, a phase of an occupation, or a person performing the occupation. Covers most phases of the job. Varies in length and degree of coverage. May also be a fact sheet, series of tables, etc. Usually, but not necessarily, in prose style. May be newspaper, magazine, or other publication.
M-Community survey economic report, job analysis	Very accurate, highly statistical, comprehensive reports made as the result of local, national, or industrial studies. Professional studies not easily adapted to student use.
N-Other	Specialized occupational studies, general occupational reviews, technical reports, or portions thereof, if applicable, and other miscellaneous occupational information. Information presented by types other than those listed above should be accounted for here. Includes occupations in relation to specific college curricula.

TSOPI 14026

X

	Recommendation
1-Highly recommended	Maximum adherence to NVGA Standards. Adequately meets most of the points outlined. A very high caliber publication--comprehensive, authentic, objective, readable, and up-to-date.
2-Recommended	General adherence to NVGA Standards. Adequately meets more than half the points outlined. A high caliber publication--authentic, objective, readable, up-to-date, but not necessarily as comprehensive.
3-Useful	Does not adequately meet NVGA Standards because limited in scope. However, contains information helpful to students making it worth including in an occupational file or library. In all cases, applicable information is authentic, objective, readable and timely.

UNIT VI - DIMENSIONING

ACHIEVEMENT TEST

Write the numbers 1 to 15 and write the letter T or F (True or False) after each number, whichever correctly describes the statements below.

1. Dimension and extension lines are drawn to the same thickness.
2. They should be drawn very heavy.
3. Arrowheads must not be drawn freehand.
4. Most employers prefer the solid-head type of arrowhead.
5. The solid-type head is made thinner and longer than the open-head type.
6. When drawn properly, arrowheads improve the appearance of a drawing.
7. Employers do not particularly care whether a drawing is neat or sloppy, so long as it is accurate.
8. Depending on drawing size, arrowheads will vary slightly.
9. All dimensions should read from the bottom or right side of the drawing.
10. The extension lines begin approximately $\frac{1}{16}$ inch away from the drawing.
11. The placing of notes on drawings should be discouraged.
12. You can confuse a workman by placing too many dimensions on a drawing.
13. There are no hard- and- fast rules for dimensioning.
14. Learning shop procedures will help you dimension better.
15. A good rule to remember when drawing fractions is that the total fraction height is twice that of the integer.

14100

UNIT VIII - SECTIONAL DRAWINGS

ACHIEVEMENT TEST

Write the numbers 1 to 10 and write the letter T or F (True or False) after each number, whichever correctly describes the statements below.

1. The preferred angle for drawing cross-hatch lines is 45°.

2. Cross-hatch lines are drawn $\frac{1}{8}$ inch apart, each distance being measured by a ruler.

3. A full section is one which shows one view of the drawing as though it were cut in half.

4. Full sections are used only for cylindrical objects.

5. A half section is one which shows one view of a drawing as though it were cut in half.

6. A revolved section is used when the views of a drawing do not fully describe the shape of the part.

7. Shafts, pins, screws, rivets, and bolts are always cross hatched.

8. The advantage of the half section is that one half of the drawing shows an interior view and the other half an exterior view.

9. Without sectional views, it would be extremely difficult to illustrate some drawings.

10. Full sections eliminate many dashed lines, which often make reading or visualizing difficult.

Draw the V-belt pulley shown below. Lay out the centerline first; then complete a circular view before projecting to a principal view. Draw the pulley in half section. Note how clearly the half section describes the pulley. The double-spaced 45° cross-hatched lines indicate that the material is steel. Cross hatch lines are drawn in after all dimensions have been indicated.

VT 011 176
Garment Alterations. An Adult Training Course for Selected Occupations in Clothing Services.

New York State Education Dept., Albany. Bureau of Continuing Education Curriculum Services.
MF AVAILABLE IN VT-ERIC SET.
The Publications Distribution Unit, State Education Department, Albany, New York 12224.
PUB DATE - 70 74p.

DESCRIPTORS - *TEACHING GUIDES; *ADULT EDUCATION PROGRAMS; *CLOTHING INSTRUCTION; INSTRUCTIONAL MATERIALS; *OCCUPATIONAL HOME ECONOMICS; *NEEDLE TRADES; SEAMSTRESSES; PROGRAM GUIDES

ABSTRACT - Designed to aid adult education directors and instructors in developing and implementing courses in clothing construction, this guide provides instructional techniques and methods for preparing trainees to become competent garment fitters, tailor's helpers, seamstresses, women's garment finishers, and garment rippers. Contents are divided into three sections, the first of which is concerned with administrative considerations, including utilization of the advisory committee, selection of instructor and trainees, facilities, and organizing and promoting the course. Section II presents a suggested state course of study, broken down into six units or major areas of learning, including: (1) Use and Care of Fabrics, (2) Selection, Use, and Care of Sewing Equipment, (3) Techniques of Sewing, (4) Elements and Principles of Design, (5) Preparation for Employment, and (6) Management of a Garment Alterations Business. Units provide required job competencies, motivating procedures, suggested learning experiences, and instructional materials and references. Ways to adapt the state course to local situations are presented in Section III. Samples of instructional aids are appended and a bibliography is also included. (AW)

INTRODUCTION*

A program of vocational horticulture must provide meaningful personal experience for students enrolled along with formal classroom and laboratory experiences. Experiences may be obtained through supervised occupational experience programs. Occupational experience programs should include objectives which all students can obtain. Students should achieve the following objectives as part of their supervised occupational experience programs.

1. The supervised program should provide experiences necessary for the development of abilities important to the students success in a horticultural occupation.

2. The program should include a financial arrangement providing an equitable division of the costs and returns for the parties involved.

3. The program should provide opportunities for a financial return to the student each year.

4. The program should be continued and expanded to increase size, scope, and managerial responsibilities during each school year.

5. The program should be commensurate with the interests and personal capabilities of the student as well as his resources in terms of labor and capital.

6. The program should provide experience in risk bearing, financing, marketing and the use of credit when possible.

7. The program should provide opportunities for experience in decision making as well as managerial skills.

8. The program should utilize the occupational opportunities available in the school community.

9. The program should fully appraise the student of all the advantages and disadvantages of making horticulture a lifetime career.

10. The program should help the student develop proper attitudes toward work, the employer, fellow employees, customers and the industry as a whole.

11. The program should assist in helping the student make a firm vocational choice.

This book is a record of the students supervised occupational experience program. This book will be used as one means of judging the students success in achieving the above objectives through the experience program he has chosen through conferences with his parents and teacher. The student should read all instructions carefully and record all material in a complete, correct and clear manner so any person who examines this book can judge as to the worth of the student and his experience program.

MY OCCUPATIONAL GOALS IN HORTICULTURE

I am interested in the following horticultural occupations. (check one or two)

_____	Florist	_____	Produce Merchandising
_____	Horticultural Mechanics	_____	Greenhouse Production
_____	Landscaping	_____	Horticultural Supply Service
_____	Turf Management	_____	Horticultural Education
_____	Garden Center	_____	Other Horticultural Occupations

With the aid of your teacher, describe the education and experience needed to reach your occupational goal, and outline your plans for reaching this goal. Your plan should cover the period from the present until you enter into your chosen occupational area. Make your plans as specific as possible including dates, hours of experience, capital investments, and similar items.

MY FIRST OCCUPATIONAL GOAL	PLANS FOR REACHING MY GOAL
EXPERIENCE NEEDED:	
EDUCATION NEEDED:	
COST:	
OTHER:	

MY SECOND OCCUPATIONAL GOAL	PLANS FOR REACHING MY GOAL
EXPERIENCE NEEDED:	
EDUCATION NEEDED:

MY OCCUPATIONAL EXPERIENCE PROGRAM

Keeping in mind the goals that you outlined on the previous page, you should plan your experience program in such a way as to aid you in attaining your occupational goals. In order to get an overall view of the methods you will use during your vocational horticulture program, you should record a brief description of your goals for each of the areas listed and indicate the year in which you intend to achieve that goal.

1ST YEAR	2ND YEAR	3RD YEAR	4TH YEAR
PRODUCTION PROJECTS:			
IMPROVEMENT PROJECTS:			
IN-SCHOOL PROJECTS:			
CO-OP PROGRAM:			
FFA OR OTHER YOUTH ORGANIZATIONS:			
NET WORTH:

_____

THE HORTICULTURAL BUSINESS OR SERVICE WHERE I WORK

After you have found an employer, with the aid of your teacher, in your chosen occupation you should learn about the horticultural activities of this business or service. This will help you to further develop your cooperative education program.

In the space below give a brief description of the business or service where you are to be employed as a trainee in terms of products produced, merchandised or processed; size or volume of business; equipment or facilities available; and the number of people employed and their major responsibilities.

EMPLOYMENT AGREEMENT FOR THE SUPERVISED OCCUPATIONAL EXPERIENCE PROGRAM

OF A STUDENT OF VOCATIONAL HORTICULTURE

To insure a permanent basis of understanding and to promote better working relations, this agreement is established on _____ 19 ___.

The work will start on _____ 19 ___ and will terminate on or about _____ 19 ___. (Subject to further agreement for continued work)

Name of Business or Service: _____

The person in industry who will be responsible for the training of the student will be _____

The usual working hours will be as follows:

When attending school _____

While not attending school _____

Provisions for time off are _____

Provisions for overtime are _____

Liability insurance coverage is _____

Compensation during the trial period will be _____

Compensation during the remainder of the agreement will be _____

The student will be paid on (day) _____

THE EMPLOYER AGREES:

To provide the student with opportunities to learn how to do well as many jobs as possible, with particular reference to those contained in the training plan.

To coach the student in the ways which he has found desirable in doing his work and handling his problems.

To make an honest appraisal of the student's performance on the job at the end of a specific period agreed upon.

To give the instructor time for short conferences regarding the progress of the student.

To avoid subjecting the student to unnecessary or unusual hazards.

To notify the parent and school immediately in case of accident, sickness, or any other serious problem which might arise.

To permit the teacher of the student to take whatever time necessary for supervisory visits to the industry.

TEAR OUT ON THIS LINE

THE STUDENT AGREES:

To notify the employer at once when found necessary to be absent from work for a justifiable cause.

To do a good day's work according to his age and ability, recognizing that the employer must profit from his labor in order to justify hiring him.

To keep the employer's interest in mind, being punctual, dependable, and loyal.

To follow instructions, avoid unsafe acts and be alert to unsafe conditions.

To be courteous and considerate of the employer, his family and others.

To keep such records of his work experience and to make such reports as required by the school.

THE INSTRUCTOR, ON BEHALF OF THE SCHOOL, AGREES:

To visit the student on the job at frequent intervals for the purpose of instruction and to insure that he gets the most out of his experience.

To show discretion in the time and circumstances of these visits, especially during emergency periods when the work is pressing.

THE PARENT AGREES:

To assist in promotion of the value of the student's experience by cooperating with the employer and the teacher of vocational horticulture.

To satisfy himself in regard to living conditions made available to the student if the student is housed away from home.

ALL PARTIES AGREE:

That the initial working days be regarded as a trial period to allow the student time to adjust and prove himself.

That in the event of difficulties in the interpretation of the terms of this agreement, the vocational horticulture instructor shall be the mediator.

This agreement may be terminated for cause at any time by either party after due notice, but not without first consulting the school.

Foreword

The need for people skilled in altering garments is increasing. Today's shopper purchases more ready-to-wear garments and is more demanding regarding their quality and fit. Also, technological developments in the field of textiles and clothing are constantly appearing which require new competencies in the handling of fabrics. This publication is designed to help the director of adult education and the instructor develop a course for individuals who have competencies in clothing construction and who wish to expand them into salable skills for the job market.

Appreciation is expressed to Jean McCracken, continuing education clothing instructor, Guilderland Central School, for her efforts in developing the instructional materials. The Bureau is grateful to Selma Karam, merchandise manager and counselor of Softline Home Furnishings and Fabric Division, The Boston Store, Utica, who provided information relative to the training needs of personnel in alteration departments of retail businesses.

Assistance relating to content was provided by Janet E. Popp, Associate in the Bureau of Home Economics Education. Nelson S. Maurer, Associate in the Bureau of Continuing Education Curriculum Development, coordinated the project and prepared the manuscript for publication.

Message to the Instructor

This publication is designed to provide instructional techniques and methods to help prepare individuals to become competent garment fitters, tailor's helpers, seamstresses, women's garment finishers, and garment rippers. Trainees for this course should have some proficiency in clothing construction. A carefully planned screening process will help locate individuals who can best profit from this program.

The course is organized to provide sequential units to help meet the varying ability levels and needs of the trainees. Methods for organizing and promoting the course are given in Section I. A suggested course of study composed of six units or major areas of learning is presented in Section II. Also included are required job competencies, motivating procedures, and suggested learning experiences. Ways to adapt the State course to the local situation are suggested in Section III. Samples of instructional aids are included in the Appendix, and useful books and pamphlets are listed in the Bibliography.

Other Department publications that will be helpful include *Tips for Teaching Textiles and Clothing*, *Resource Courses for Planning Local Adult Homemaking Programs*, and *Training Guide for Clothing Services*. The services of the staff of the Bureau of Home Economics Education are available for help in organizing local courses, training instructors, and working with advisory committees.

Instructors are urged to communicate to this Bureau their comments regarding the usefulness of the publication and to suggest additional materials that might be included in a subsequent revision.

EVALUATION OF OCCUPATIONAL EXPERIENCE

Section A

The purpose of this page is to help you evaluate your entire program of occupational experience at the close of the year or at it's conclusion. Pages 1, 2, and 3 list some of the goals which you set up for yourself. In making your evaluation consider how many of these goals you were able to achieve and the quality of your work in meeting these goals. List each project of work experience on a separate line.

In section A rate each part of your program in terms of E = Excellent, G = Good, F = Fair, and P = Poor.

Rating of Occupational Experience

ABSTRACT - Prepared by the Navy Training Publications Center for the Bureau of Naval Personnel, this study guide is designed for use by all personnel of the Regular Navy and Naval Reserve who are studying for advancement in the Aviation Maintenance Administrationman rating. Professional qualifications for advancement to the rates of AZ1 and AZC provide a base for the content. This manual is divided into seven chapters: (1) Aviation maintenance administration rating, (2) Maintenance management organization, (3) Supervision and Administration, (4) Maintenance control, (5) Data services and maintenance data analysis, (6) Quality assurance, and (7) Material control. A film list and a reading list are included. (GEB)

PREFACE

This Navy Training Course is one of two training courses prepared especially for all enlisted personnel of both the Regular Navy and Naval Reserve who are studying for advancement in the Aviation Maintenance Administrationman (AZ) rating. As indicated by the title, the course is based on the professional qualifications for advancement to the rates of AZ1 and AZC, as stated in the Manual of Qualifications for Advancement in Rating, NavPers 18068 (Series). Each person should familiarize himself with these qualifications prior to starting work on this course. A reading list, which includes other publications recommended as study material, is provided in the front of the book.

Combined with the necessary practical experience, the completion of this course will greatly assist the AZ2 and AZ1 in preparing for advancement examinations. This training course should also be valuable as a review source for the more senior rates.

This training course was prepared by the Navy Training Publications Center, Memphis, Tennessee, for the Bureau of Naval Personnel. Credit is given to personnel of the Aviation Maintenance Administrationman Course, Class A, and the Data Analysis Course, Class C, located at NATTC, Memphis, Tennessee, and to the Naval Air Systems Command for technical reviews of the manuscript.

THE UNITED STATES NAVY

GUARDIAN OF OUR COUNTRY

The United States Navy is responsible for maintaining control of the sea and is a ready force on watch at home and overseas, capable of strong action to preserve the peace or of instant offensive action to win in war.

It is upon the maintenance of this control that our country's glorious future depends; the United States Navy exists to make it so.

WE SERVE WITH HONOR

Tradition, valor, and victory are the Navy's heritage from the past. To these may be added dedication, discipline, and vigilance as the watchwords of the present and the future.

At home or on distant stations we serve with pride, confident in the respect of our country, our shipmates, and our families.

Our responsibilities sober us; our adversities strengthen us.

Service to God and Country is our special privilege. We serve with honor.

THE FUTURE OF THE NAVY

The Navy will always employ new weapons, new techniques, and greater power to protect and defend the United States on the sea, under the sea, and in the air.

Now and in the future, control of the sea gives the United States her greatest advantage for the maintenance of peace and for victory in war.

Mobility, surprise, dispersal, and offensive power are the keynotes of the new Navy. The roots of the Navy lie in a strong belief in the future, in continued dedication to our tasks, and in reflection on our heritage from the past.

Never have our opportunities and our responsibilities been greater.

READING LIST

Aviation Maintenance Administrationman 3 & 2, NavPers 10391-A

Navy Security Manual, OpNav Instruction 5510.1 (Series)

Aircraft Accounting System, OpNav Instruction 5442.2 (Series)

Navy Correspondence Manual, SecNav Instruction 5216.5 (Series)

Navy Aircraft Engine Management Program, BuWeps Instruction 13700.1

Navy Aircraft Maintenance Program (Chapters 7, 8, 10, 11, 12, and 15), NavAir Instruction 4700.2 (Series)

Aviation 3-M Manual (Chapters I, II, III, IV, V, VII, and VIII)

USAFI TEXTS

United States Armed Forces Institute (USAFI) courses for additional reading and study are available through your Educations Services' Officer.* The following course is recommended:

E 545 Office Management

*"Members of the United States Armed Forces Reserve components, when on active duty, are eligible to enroll for USAFI courses, services, and materials if the orders calling them to active duty specify a period of 120 days or more, or if they have been on active duty for a period of 120 days or more, regardless of the time specified on the active duty orders."

14183

CHAPTER 1

AVIATION MAINTENANCE ADMINISTRATIONMAN RATING

This training course is designed to aid the AZ2 in preparing for advancement to AZ1 and the AZ1 in preparing for advancement to AZC. It is based primarily on the professional requirements or qualifications for AZ1 and AZC, as specified in the current edition of the Manual of Qualifications for Advancement in Rating, NavPers 18068. In preparing for advancement examinations, this course should be studied in conjunction with Military Requirements for Petty Officers 1 & C, NavPers 10057-B. The latter covers the military requirements for all senior petty officers.

In preparing this training course, every effort has been made to cover professional matters adequately and yet within reasonable bounds. It has been designed to give the prospective AZ1 or AZC a good working knowledge of all subjects covered by the professional qualifications for advancement. It includes some new material required as a result of new or revised maintenance programs and qualification changes. The AZ1 and AZC are expected to be proficient in the field of maintenance administration.

Since senior AZ's are largely occupied with planning, supervision, and training, this course has been slanted for maximum use in these phases. A course of this type cannot present all the detailed knowledge which is required in every duty assignment. Particular details should always be checked in applicable manuals or instructions.

A brief summary of the contents of this training course is given in the following paragraphs.

Chapter 2 discusses organizational structure, starting at the Department of Defense level and working down to the maintenance department of aviation squadrons. This chapter is primarily concerned with relationships and responsibilities of commands concerned with naval aircraft maintenance. This chapter also contains a brief introduction to the Navy Maintenance and Material Management System. The latter part of the chapter provides information on organization principles and management functions.

Chapter 3 discusses some of the aspects of office supervision and duties of a supervisor. Included are sections on planning office arrangement, scheduling and assignment of workloads, work simplification, preparation, routing, and filing various types of correspondence and reports pertaining to aircraft maintenance, maintenance and disposal of logs and records, and the manhour accounting system.

Chapter 4 presents information on production control operations and procedures. Included are sections on planning and scheduling aircraft through various types of maintenance, aircraft acceptance and transfer, aircraft and engine accounting, and maintenance support available at Depot level activities.

Chapter 5 deals with data services and maintenance data analysis. Some of the responsibilities of data services and the analysis division are discussed along with maintenance data reports, analysis techniques, and analysis products.

Chapter 6 is concerned with quality assurance. Coverage is devoted to some of the functions in which AZ's are involved, the technical manual system, and technical library management.

Chapter 7 presents information on the aviation supply system and the material control work center. Included are sections on appropriations, operating budgets, the Federal Stock Numbering System, allowance lists, issue, turn-in, and survey of material, and the general functions of certain sections of the local supply system under the Navy Maintenance and Material Management System.

The remainder of chapter 1 is devoted to information which should be helpful in preparing for advancement. It is strongly recommended

14189

Administrative Considerations

The success of a course depends upon the competency of the people who plan and guide its development and upon the initiative of the people who provide instruction and create an effective learning environment. Some procedures which may assist in establishing the course include utilizing an advisory committee, employing a qualified instructor, screening applicants, providing adequate training facilities, and publicizing the course. Below are suggestions for implementing each of these procedures.

UTILIZATION OF AN ADVISORY COMMITTEE

An advisory committee can assist in establishing the course in the following ways:

- Securing and analyzing information concerning local opportunities for employment
- Preparing job analyses
- Suggesting content for the local curriculum
- Developing and strengthening relationships with potential employers
- Interpreting the program to the general public
- Evaluating successful practices

The appointment of advisory committee members is made cooperatively by the chief school administrator, director of adult education, and home economics personnel. Representation should be from such groups as secondary home economics teachers, employment service personnel, local employers, and related trade and professional organizations. Some decisions that need to be determined before selecting an advisory committee include the purpose of the committee, rotation of committee members, and means of communicating with members to inform them of needed assistance and of any progress being made.

SELECTION OF A QUALIFIED INSTRUCTOR

The best qualified instructor for the program is a person certified in home economics education and who has had work experience in the field of garment alterations. Consultants may be used to enrich the content of the training program. The following understandings and competencies are recommended for the instructor:

- Ability to use the equipment needed to perform the identified jobs

that this material be studied carefully before beginning intensive study of the remainder of the course.

ENLISTED RATING STRUCTURE

The present enlisted rating structure includes two types of ratings: general ratings and service ratings.

GENERAL RATINGS are designed to provide paths of advancement and career development. A general rating identifies a broad occupational field of related duties and functions requiring similar aptitudes and qualifications. General ratings provide the primary means used to identify billet requirements and personnel qualifications. Some general ratings include service ratings; others do not. Both Regular Navy and Naval Reserve personnel may hold general ratings.

Subdivisions of certain general ratings are identified as SERVICE RATINGS. These service ratings identify areas of specialization within the scope of a general rating. Service ratings are established in those general ratings in which specialization is essential for efficient utilization of personnel. Although service ratings can exist at any petty officer level, they are most common at the PO3 and PO2 levels. Both Regular Navy and Naval Reserve personnel may hold service ratings.

AZ RATING

The Aviation Maintenance Administrationman rating is a general rating and is included in Navy Occupational Group IX (Aviation). There are no AZ service ratings.

Where occupational content is related, general ratings are sometimes combined at certain pay grades to form broader occupational fields. Until recently, this was true of the AZ rating. At the present time, however, the AZ rating retains its identity through the E-9 level.

Figure 1-1 illustrates the path of advancement from Airman Recruit to Master Chief Aviation Maintenanceman, Warrant Officer (W-4), or Limited Duty Officer.

Shaded areas in figure 1-1 indicate places in the enlisted path of advancement where qualified personnel may advance to Warrant Officer (W-1), and selected Commissioned Warrant Officers (W-2 and W-3) may advance to Limited Duty Officer. Personnel in enlisted rates and Warrant ranks not in a shaded area (fig. 1-1) may advance only as indicated by the connecting arrows. Additional information concerning promotion to Warrant and Commissioned Officer is presented later in this chapter.

The Manual of Qualifications for Advancement in Rating, NavPers 18068 (Series), establishes the AZ's technical responsibilities. Aviation Maintenance Administrationmen perform administrative, management, and clerical duties required in implementing and supporting the Naval Aircraft Maintenance Program; plan, schedule, and coordinate the aircraft maintenance workload; schedule special and calendar aircraft inspections and incorporation of changes and modifications to aircraft and equipment; set up and maintain status boards; collect, compile, and record data pertaining to the history, operation, maintenance, configuration, receipt, and transfer of naval aircraft and related aeronautical equipment; prepare reports and correspondence required in the Naval Aircraft Maintenance Program; determine requirements for, requisition, and control issue of change kits; requisition publications, forms, and microfilm; organize, maintain, and operate technical libraries; and perform other duties required in aircraft maintenance offices.

In addition to the above listed requirements the First Class or Chief Aviation Maintenance Administrationman should be qualified to supervise and direct the operations of production control work centers and aeronautic technical libraries; supervise the manhour accounting program; interpret directives from higher authorities; and maintain the highest possible state of quality work for which he is responsible.

Selected AZ's also perform analysis functions on the data collected under the Maintenance Data Collection System. Those AZ's selected to accomplish these functions normally complete the Data Analysis Course at NATTC Memphis prior to performing duties as a data analyst.

The AZ1 and AZC have varied types of duty billets. Each may be assigned to a billet in which he is involved with only a small portion of the duties covered by his rate, or where a large part of his duties are concerned with other areas of maintenance administration. This, however, does not mean that he is not required to keep abreast of the changing conditions and instructions pertaining to all duties of his rate. The AZ must be qualified in all phases in order that he

Figure 1-1.—Path of advancement.

may be assigned to the billet where he is most needed. The Navy cannot tailor billets to fit individual qualifications.

A wide variety of assignments is available to the AZ1 and AZC. In addition to the various types of maintenance activities afloat and ashore to which AZ personnel are assigned, the AZ1 and AZC are eligible for assignment to instructor duty as well as a number of other desirable shore billets. Most of these billets are under the management control of BuPers and are directly associated with training. Others are associated with research, testing, or evaluation. Some of the more desirable billets to which the AZ1 and AZC may be assigned are described in the following paragraphs.

1. Instructor duty is available to both the AZ1 and AZC at several Navy schools. The Aviation Maintenance Administrationman Class A Course and the Aviation Maintenance Data Analysis Class C Course located at the Naval Air Technical Training Center, Memphis, Tennessee, utilize AZ1's and AZC's as instructors.

In addition to the above listed instructor billets, the AZ1 and AZC may be assigned to instructor duty with a unit of the Naval Air Maintenance Training Group (NAMTG). Units of NAMTG are located at shore stations on both coasts. Personnel assigned to this duty are first sent to Naval Air Maintenance Training Group Headquarters at Memphis for a period of indoctrination and instruction prior to being assigned to one of the many units.

Instructor billets are normally filled on a voluntary basis. Detailed information concerning assignment to instructor duty is contained in the Enlisted Transfer Manual, NavPers 15909 (Series).

2. Chief Aviation Maintenance Administrationmen are eligible for assignment to duty with the Navy Training Publications Center (NTPC), NAS, Memphis, as Technical Writers. CPO's assigned to NTPC assist in the preparation and revision of Navy Training Courses for the Group IX ratings.

3. Chief Aviation Maintenance Administrationmen are also eligible for assignment to duty with the Naval Examining Center, Great Lakes, Illinois, as Item Writers. CPO's assigned to billets at the Examining Center assist in the preparation of servicewide advancement examinations for enlisted personnel.

4. Chief Aviation Maintenance Administrationmen are regularly assigned to various staff billets. This includes the staff of one of the major operating commands, area subordinate command staff (COMFAIR), or air wing/group staff.

5. Attaché duty is another possibility. This duty may be performed at numerous places throughout the world.

There are a number of special programs and projects to which enlisted personnel may be assigned. Some of these involve research, others may involve testing or evaluation. An example of such an assignment is with the Weapons Personnel Research Branch (WPRB), NATC, Patuxent River, Maryland. Their mission is to develop recommended personnel requirements for squadrons operating and maintaining the latest types of weapon systems.

For a listing of other special programs, reference should be made to the Enlisted Transfer Manual. Others are also announced from time to time in BuPers Notices.

Personnel may indicate their desire for assignment to a specific program or project by indicating it in the "remarks" block of their Rotation Data Card.

As a petty officer you are already aware of the importance of the AZ rating to naval aviation. Everyone from the commanding officer to the worker depends on the AZ for planning, scheduling, and coordination of the aircraft maintenance workload as well as the maintenance of records and the timely and proper distribution of related publications. As aviation progresses, improved techniques must be developed. Thus, the AZ's job involves new and greater responsibilities, and from the lowest level up, he must possess greater technical knowledge than ever before.

When advanced to AZ1 or AZC, even more responsibilities are to be yours. As a senior petty officer you must possess more than technical knowledge. You must assume greater responsibility not only for your own work, but also for the work of others who serve under you. Briefly, the AZ1 and AZC must be a supervisor, inspector, and instructor, as well as an accomplished military leader. Senior petty officers are therefore vitally concerned with the Naval Leadership Program.

As a result of the Naval Leadership Program a considerable amount of material related to naval leadership for the senior petty officer is available. Studying this material will make you aware of your many leadership responsibilities as a senior petty officer and will also be of great help in developing leadership qualities. It will not in itself, however, make you a

good leader. Leadership principles can be taught, but a good leader acquires that quality only through hard work and practice.

As you study this material containing leadership traits, keep in mind that probably none of our most successful leaders possessed all of these traits to a maximum degree, but a weakness in some traits was more than compensated for by strength in others. Critical self-evaluation will enable you to realize the traits in which you are strong, and to capitalize on them. At the same time you must strive to improve on the traits in which you are weak.

Your success as a leader will be decided, for the most part, by your achievements in inspiring others to learn and perform. This is best accomplished by personal example.

ADVANCEMENT

By this time, you are probably well aware of the personal advantages of advancement—higher pay, greater prestige, more interesting and challenging work, and the satisfaction of getting ahead in your chosen career. By this time, also, you have probably discovered that one of the most enduring rewards of advancement is the training you acquire in the process of preparing for advancement.

The Navy also profits by your advancement. Highly trained personnel are essential to the functioning of the Navy. By advancement, you increase your value to the Navy in two ways: First, you become more valuable as a technical specialist; and second, you become more valuable as a person who can supervise, lead, and train others and thus make far-reaching contributions to the entire Navy.

Since you are studying for advancement to PO1 or CPO, you are probably already familiar with the requirements and procedures for advancement. However, you may find it helpful to read the following sections. The Navy does not stand still. Things change all the time, and it is possible that some of the requirements have changed since the last time you went up for advancement. Furthermore, you will be responsible for training others for advancement; therefore, you will need to know the requirements in some detail.

HOW TO QUALIFY FOR ADVANCEMENT

To qualify for advancement, a person must:

1. Have a certain amount of time in grade.
2. Complete the required military and professional training courses.
3. Demonstrate the ability to perform all the PRACTICAL requirements for advancement by completing applicable portions of the Record of Practical Factors, NavPers 1414/1 (formerly NavPers 760).
4. Be recommended by his commanding officer.
5. Demonstrate his KNOWLEDGE by passing a written examination on (a) military requirements, and (b) professional qualifications.

Some of these general requirements may be modified in certain ways. Figure 1-2 gives an overall view of the requirements for advancement of active duty personnel; figure 1-3 gives this information for inactive duty personnel.

Remember that the requirements for advancement can change. Check with your educational services office to be sure that you know the most recent requirements.

When you are training lower rated personnel, it is a good idea to point out that advancement is not automatic. Meeting all the requirements makes a person ELIGIBLE for advancement, but it does not guarantee his advancement. Such factors as the score made on the written examination, length of time in service, performance marks, and quotas enter into the final determination of who will actually be advanced.

HOW TO PREPARE FOR ADVANCEMENT

Preparation for advancement includes studying the qualifications, working on the practical factors, studying the required Navy Training Courses, and studying any other material that may be specified. To prepare yourself for advancement or to help others prepare for advancement, you will need to be familiar with (1) the "Quals" Manual, (2) the Record of Practical Factors, NavPers 1414/1, (3) a NavPers publication called Training Publications for Advancement in Rating, NavPers 10052 (Series), and (4) Navy Training Courses. The following sections describe these materials and give some information on how to use them to the best advantage.

"Quals" Manual

The Manual of Qualifications for Advancement in Rating, NavPers 18068 (Series), gives the minimum requirements for advancement to

REQUIREMENTS*	E1 to E2	E2 to E3	#† E3 to E4	#E4 to E5	† E5 to E6	† E6 to E7	† E7 to E8	† E8 to E9
SERVICE	4 mos. service— or completion of recruit training.	6 mos. as E-2.	6 mos. as E-3	12 mos. as E-4	24 mos. as E-5.	36 mos. as E-6. 8 years total enlisted service.	36 mos as E-7. 8 of 11 years total service must be enlisted.	24 mos. as E-8. 10 of 13 years total service must be enlisted.
SCHOOL	Recruit Training.		Class A for PR3, DT3, PT3, AME 3, HM 3, PN 3, FTB 3, MT 3,			Class B for AGC MUC, MNC.††		
PRACTICAL FACTORS	Locally prepared check-offs.	Record of Practical Factors, NavPers 1414/1, must be completed for E-3 and all PO advancements.						
PERFORMANCE TEST			Specified ratings must complete applicable performance tests before taking examinations.					
ENLISTED PERFORMANCE EVALUATION	As used by CO when approving advancement.	Counts toward performance factor credit in advancement multiple.						
EXAMINATIONS**	Locally prepared tests.	See below.	Navy-wide examinations required for all PO advancements.				Navy-wide, selection board.	
RATE TRAINING MANUAL (INCLUDING MILITARY REQUIREMENTS)		Required for E-3 and all PO advancements unless waived because of school completion, but need not be repeated if identical course has already been completed. See NavPers 10052 (current edition).					Correspondence courses and recommended reading. See NavPers 10052 (current edition).	
AUTHORIZATION	Commanding Officer	Naval Examining Center						

* All advancements require commanding officer's recommendation.
† 1 year obligated service required for E-5 and E-6; 2 years for E-7, E-8 and E-9.
# Military leadership exam required for E-4 and E-5.
** For E-2 to E-3, NAVEXAMCEN exams or locally prepared tests may be used.
†† Waived for qualified EOD personnel.

Figure 1-2.—Active duty advancement requirements.

PERFORMANCE TESTS			Specified ratings must complete applicable performance tests before taking examination.					
DRILL PARTICIPATION	Satisfactory participation as a member of a drill unit in accordance with BUPERSINST 5400.42 series.							
PRACTICAL FACTORS (INCLUDING MILITARY REQUIREMENTS)	Record of Practical Factors, NavPers 1414/1, must be completed for all advancements.							
RATE TRAINING MANUAL (INCLUDING MILITARY REQUIREMENTS)	Completion of applicable course or courses must be entered in service record.							
EXAMINATION	Standard Exam		Standard Exam required for all PO Advancements. Also pass Military Leadership Exam for E-4 and E-5.					Standard Exam, Selection Board.
AUTHORIZATION	Commanding Officer		Naval Examining Center					

* Recommendation by commanding officer required for all advancements.

† Active duty periods may be substituted for training duty.

Figure 1-3.—Inactive duty advancement requirements.

each rate. This manual is usually called the "Quals" Manual, and the qualifications themselves are often called "quals." The qualifications are of two general types: (1) military requirements, and (2) professional or technical qualifications. Military requirements apply to all rates (pay grades). Professional qualifications are technical or professional requirements that are directly related to the work of each rate (pay grade) within career fields.

Both the military requirements and the professional qualifications are divided into subject matter groups. Then, within each subject matter group, they are divided into PRACTICAL FACTORS and KNOWLEDGE FACTORS.

The qualifications for advancement and a bibliography of study materials are available in your educational services office. The "Quals" Manual is changed more frequently than Navy Training Courses are revised. By the time you are studying this training course, the "quals" may have been changed. Never trust any set of "quals" until you have checked the change number against an UP-TO-DATE copy of the "Quals" Manual.

In training others for advancement, emphasize these three points about the "quals":

1. The "quals" are the MINIMUM requirements for advancement. Personnel who study MORE than the required minimum will have a great advantage when they take the written examinations for advancement.

2. Each "qual" has a designated rate level—chief, first class, second class, or third class. You are responsible for meeting all "quals" specified for the rate level to which you are seeking advancement AND all "quals" specified for lower rate levels.

The written examinations for advancement will contain questions relating to the practical factors AND to the knowledge factors of BOTH the military requirements and the professional qualifications.

Record of Practical Factors

A special form known as the Record of Practical Factors, NavPers 1414/1, is used to record the satisfactory performance of the practical factors. This form lists all military and all professional practical factors. Whenever a person demonstrates his ability to perform a practical factor, appropriate entries must be made in the DATE and INITIAL columns. As a PO1 or CPO, you will often be required to check the practical factor performance of lower rated personnel and to report the results to your supervising officer.

As changes are made periodically to the "Quals" Manual, new forms of NavPers 1414/1 are provided when necessary. Extra space is allowed on the Record of Practical Factors for entering additional practical factors as they are published in changes to the "Quals" Manual. The Record of Practical Factors also provides space for recording demonstrated proficiency in skills which are within the general scope of the rate but which are not identified as minimum qualifications for advancement. Keep this in mind when you are training and supervising other personnel. If a person demonstrates proficiency in some skill which is not listed in the "quals" but which is within the general scope of the rate, report this fact to the supervising officer so that an appropriate entry can be made in the Record of Practical Factors.

When you are transferred, the Record of Practical Factors should be forwarded with your service record to your next duty station. It is a good idea to check and be sure that this form is actually inserted in your service record before you are transferred. If the form is not in your record, you may be required to start all over again and requalify in practical factors that have already been checked off. You should also take some responsibility for helping lower rated personnel keep track of their practical factor records when they are transferred.

A second copy of the Record of Practical Factors should be made available to each man in pay grades E-3 through E-8 for his personal record and guidance.

NavPers 10052

Training Publications for Advancement in Rating, NavPers 10052 (Series) is a very important publication for anyone preparing for advancement. This publication lists required and recommended Navy Training Courses and other reference material to be used by personnel working for advancement. NavPers 10052 (Series) is revised and issued once each year by the Bureau of Naval Personnel. Each revised edition is identified by a letter following the NavPers number. When using this publication, be SURE you have the most recent edition.

The required and recommended references are listed by rate level in NavPers 10052 (Series). It is important to remember that you are responsible for all references at lower rate

14196

levels, as well as those listed for the rate to which you are seeking advancement.

Navy Training Courses that are marked with an asterisk (*) in NavPers 10052 (Series) are MANDATORY at the indicated rate levels. A mandatory training course may be completed by (1) passing the appropriate Enlisted Correspondence Course that is based on the mandatory training course; (2) passing locally prepared tests based on the information given in the mandatory training course; or (3) in some cases, successfully completing an appropriate Navy school.

When training personnel for advancement, do not overlook the section of NavPers 10052 (Series) which lists the required and recommended references relating to the military requirements for advancement. All personnel must complete the mandatory military requirements training course for the appropriate rate level before they can be eligible to advance. Also, make sure that personnel working for advancement study the references which are listed as recommended but not mandatory in NavPers 10052 (Series). It is important to remember that ALL references listed in NavPers 10052 (Series) may be used as source material for the written examinations, at the appropriate levels.

Navy Training Courses

There are two general types of Navy Training Courses. RATING COURSES (such as this one) are prepared for most enlisted rates, giving information that is directly related to the professional qualifications. BASIC COURSES give information that applies to more than one rate.

Navy Training Courses are revised from time to time to bring them up to date. The revision of a Navy Training Course is identified by a letter following the NavPers number. You can tell whether a Navy Training Course is the latest edition by checking the NavPers number (and the letter following the number) in the most recent edition of List of Training Manuals and Correspondence Courses, NavPers 10061 (Series).

Navy Training Courses are designed for the special purpose of helping naval personnel prepare for advancement. By this time, you have probably developed your own way of studying these courses. Some of the personnel you train, however, may need guidance in the use of Navy Training Courses. Although there is no single "best" way to study a training course, the following suggestions have proved useful for many people.

1. Study the military requirements and the professional qualifications for your rate before you study the training course, and refer to the "quals" frequently as you study. Remember, you are studying the training course primarily to meet these "quals."

2. Before you begin to study any part of the training course intensively, get acquainted with the entire course. Read the preface and the table of contents. Check through the index. Thumb through the course without any particular plan, looking at the illustrations and reading bits here and there as you see things that interest you.

3. Look at the training course in more detail, to see how it is organized. Look at the table of contents again. Then, chapter by chapter, read the introduction, the headings, and the subheadings. This will give you a pretty clear picture of the scope and content of the book.

4. When you have a general idea of what is in the training course and how it is organized, fill in the details by intensive study. In each study period, try to cover a complete unit—it may be a chapter, a section of a chapter, or a subsection. The amount of material you can cover at one time will vary. If you know the subject well, or if the material is easy, you can cover quite a lot at one time. Difficult or unfamiliar material will require more study time.

5. In studying each unit, write down questions as they occur to you. Many people find it helpful to make a written outline of the unit as they study, or at least to write down the most important ideas.

6. As you study, relate the information in the training course to the knowledge you already have. When you read about a process, a skill, or a situation, ask yourself some questions. Does this information tie in with past experience? Or is this something new and different? How does this information relate to the qualifications for advancement?

7. When you have finished studying a unit, take time out to see what you have learned. Look back over your notes and questions. Without looking at the training course, write down the main ideas you have learned from studying this unit. Do not just quote the book. If you cannot give these ideas in your own words, the chances are that you have not really mastered the information.

8. Use Enlisted Correspondence Courses whenever you can. The correspondence courses

14197

well on its way to becoming a bad habit. You will have to learn the difference between oversupervising and not supervising enough. No one can do his best work with a supervisor constantly supervising. On the other hand, you cannot turn an entire job over to an inexperienced person and expect him to do it correctly without any help or supervision.

In training lower rated personnel, emphasize the importance of learning and using correct terminology. A command of the technical languages of your occupational field enables you to receive and convey information accurately and to exchange ideas with others. A person who does not understand the precise meaning of terms used in connection with his work is definitely at a disadvantage when he tries to read official publications relating to his work. He is also at a great disadvantage when he takes the examination for advancement. To train others in the correct use of technical terms, you will need to be very careful in your own use of words. Use correct terminology and insist that personnel you are supervising use it too.

You will find the Record of Practical Factors, NavPers 1414/1, a useful guide in planning and carrying out training programs. From this record, you can tell which practical factors have been checked off and which ones have not yet been done. Use this information to plan a training program that will fit the needs of the personnel you are training.

On-the-job training is usually controlled through daily and weekly work assignments. When you are working on a tight schedule, you will generally want to assign each person to the part of the job that you know he can do best. In the long run, however, you will gain more by assigning personnel to a variety of jobs so that each person can acquire broad experience. By giving people a chance to do carefully supervised work in areas in which they are relatively inexperienced, you will increase the range of skills of each person and thus improve the flexibility of your working group.

Working With Others

As you advance to PO1 or CPO, you will find that many of your plans and decisons affect a large number of people, some of whom are not even in your own occupational field. It becomes increasingly important, therefore, for you to understand the duties and the responsibilities of personnel in other ratings. Every petty officer in the Navy is a technical specialist in his own field. Learn as much as you can about the work of others, and plan your own work so that it will fit into the overall mission of the organization.

Keeping Up With New Developments

Practically everything in the Navy—policies, procedures, publications, equipment, systems—is subject to change and development. As a PO1 or CPO, you must keep yourself informed about changes and new developments that affect you or your work in any way.

Some changes will be called directly to your attention, but others will be harder to find. Try to develop a special kind of alertness for new information. When you hear about anything new in the Navy, find out whether there is any way in which it might affect your work. If so, find out more about it.

SOURCES OF INFORMATION

As a PO1 or CPO, you must have an extensive knowledge of the references to consult for accurate, authoritative, up-to-date information on all subjects related to the military and professional requirements for advancement.

Publications mentioned in this chapter are subject to change or revision from time to time—some at regular intervals, others as the need arises. When using any publication that is subject to revision, make sure that you have the latest edition. When using any publication that is kept current by means of changes, be sure you have a copy in which all official changes have been made.

A list of training courses and publications that will be helpful as references and for additional study in preparing for advancement is included in the reading list at the beginning of this text. Additional training courses that are applicable are available through your educational services officer.

In addition to training courses and publications, training films furnish a valuable source of supplementary information. A selected list of training films that may be useful appear in the appendixes of this training course. Other films that may also be helpful are listed in the U.S. Navy Film Catalog, NavAir 10-1-777.

ADVANCEMENT OPPORTUNITIES FOR PETTY OFFICERS

Making chief is not the end of the line as far as advancement is concerned. Proficiency pay,

14199

- Proficiency in basic sewing methods, tailoring techniques, and altering different types of garments
- Comprehensive knowledge of textiles including finishes, characteristics, and weaves
- General understanding of the practices of potential employers
- Concepts of current styles and fit of clothing
- Skill in using teaching techniques

SELECTION OF TRAINEES

The trainees should have certain basic sewing skills before they are accepted into the course including the ability to:

- Use a home-type sewing machine
- Use a commercial pattern
- Cut fabric accurately
- Use marking, cutting, and measuring equipment
- Sew a plain seam
- Construct and attach a collar
- Apply a set-in sleeve
- Apply a facing
- Put in a hem

Pretesting of trainees will help determine their competence and facilitate the selection of individuals for the course. This may be done before or during the first lesson. Factors determining the number and type of pretests to use include the jobs for which training is offered, time available for testing, and the number of applicants for the course.

Suggested methods for screening and/or pretesting trainees are:

- Encourage the applicant to assess his qualifications for the course by providing requirements in the promotional materials.
- Evaluate garments made by the applicant to quickly assess the level of his ability.
- Interview applicant to ascertain his motivation for taking the course, sewing background, basic understanding of construction methods, and ability to communicate ideas.

advancement to Senior (E-8) and Master (E-9) Chief, and advancement to Warrant Officer and Commissioned Officer are among the opportunities that are available to qualified petty officers. These special paths of advancement are open to personnel who have demonstrated outstanding professional ability, the highest order of leadership and military responsibility, and unquestionable moral integrity.

PROFICIENCY PAY

The Career Compensation Act of 1949, as amended, provides for the award of proficiency pay to designated enlisted personnel who possess special proficiency in a military skill. Proficiency pay is given in addition to regular pay and allowances and any special or incentive pay to which you are entitled. Certain enlisted personnel in pay grades E-4 through E-9 are eligible for proficiency pay. Proficiency pay is allocated by ratings and NEC's, with most awards being given in the ratings and NEC's which are designated as critical. The eligibility requirements for proficiency pay are subject to change. In general, however, you must be recommended by your commanding officer, have a certain length of time on continuous active duty, and be career designated.

ADVANCEMENT TO SENIOR AND MASTER CHIEF

Chief petty officers may qualify for the advanced grades of Senior and Master Chief which are now provided in the enlisted pay structure. These advanced grades provide for substantial increases in pay, together with increased responsibilities and additional prestige. The requirements for advancements to Senior and Master Chief are subject to change but, in general, include a certain length of time in grade, a certain length of time in the naval service, a recommendation by the commanding officer, and a sufficiently high mark on the Navy-wide examination. The final selection for Senior and Master Chief is made by a regularly convened selection board.

Examination Subjects

Qualifications for advancement to Senior Chief Petty Officer and Master Chief Petty Officer have been developed and published in the Manual of Qualifications for Advancement in Rating, NavPers 18068 (Series). They officially establish minimum military and professional qualifications for Senior and Master Chief Petty Officers.

Training Publications for Advancement in Rating, NavPers 10052 (Series) contains a list of study references which may be used to study for both military and professional requirements.

The satisfactory completion of the correspondence course titled Navy Regulations, NavPers 10740-A, is mandatory for advancement to E-8, and the course titled Military Justice in the Navy, NavPers 10993, is required of all personnel advancing to E-9.

ADVANCEMENT TO WARRANT AND COMMISSIONED OFFICER

The Warrant Officer program provides opportunity for advancement to warrant rank for E-6 and above enlisted personnel. E-6's, to be eligible, must have passed an E-7 rating exam prior to selection.

The LDO program provides a path of advancement from warrant officer to commissioned officer. LDO's are limited, as are warrants, in their duty, to the broad technical fields associated with their former rating.

If interested in becoming a warrant or commissioned officer, ask your educational services officer for the latest requirements that apply to your particular case.

Chapter 2

MAINTENANCE MANAGEMENT ORGANIZATION

Our fast moving world with its scientific and technological advances and the role of our nation in international affairs have thrust upon the United States tremendous responsibilities and challenges. The organization of the Department of Defense is the method by which the efforts of the military and civilian personnel are systematically coordinated to shoulder the responsibilities and to meet these challenges.

Senior Aviation Maintenance Administrationmen deal not only with other divisions and departments within their own activity, but also deal with various commands and offices of the Department of the Navy. The need for a thorough understanding of the organizational structure through which the AZ meets his responsibilities cannot be overemphasized.

Organization is the means by which management plans, directs, coordinates, and controls operations and activities. It is the division of work into logical groupings of functions and the establishment of channels of authority, communications, and control between the personnel assigned to the various functional groupings.

Able, dedicated personnel can accomplish any assigned task, no matter how poorly they are organized; however, with a good organization, the task can be accomplished more effectively and efficiently. The objective of modern management is to accomplish assigned tasks effectively, efficiently, and economically.

The purpose of this chapter is to acquaint the senior AZ with some of the organizational aspects of the Department of Defense and the Department of the Navy. Navy organization is continuously changing to keep pace with requirements created by improvements in procedures, technological advances, modifications in functions, and new management concepts.

Contained within the pages of the Naval Aircraft Maintenance Program, NavAir Instruction 4700.2 (Series), and the Naval Aviation Maintenance and Material Management Manual (3-M) are all the essential elements to a smooth functioning aircraft maintenance program. However, in order to understand the position of the maintenance effort in the overall plan of Navy operations, certain command relationships and the general aircraft maintenance responsibilities assigned these commands must first be established.

DEPARTMENT OF DEFENSE

The Department of Defense was created as a part of a comprehensive program designed to provide for the future security of the United States. This is accomplished through the establishment of integrated policies and procedures for departments, agencies, and functions of the government relating to national security.

ORGANIZATION AND FUNCTIONS

The Department of Defense consists of the Secretary of Defense, the Deputy Secretary of Defense, the Defense Staff offices, the Joint Chiefs of Staff and the Joint Staff, the three military departments and the services within, the unified and specified commands, and other agencies that the secretary of Defense may establish to meet specific requirements.

The Defense Staff offices and the Joint Chiefs of Staff provide immediate staff assistance and advice to the Secretary of Defense. They are organized separately but function in full coordination and cooperation. The Defense Staff offices consist of the offices of the Director of Defense Research and Engineering, the various Assistant Secretaries of Defense, the General Counsel of the Department of Defense, and such other staff offices that may be established by the Secretary of Defense to assist him in carrying out his duties and responsibilities.

Each military department is separately organized under its own secretary.

Commanders of unified and specified commands have full operational control over their assigned forces and are responsible to the President and the Secretary of Defense for the accomplishment of assigned military missions.

The Department of Defense maintains and employs armed forces for the following:

1. To support and defend the Constitution of the United States against all enemies, foreign and domestic.
2. To insure by timely and effective military actions, the security of the United States, its possessions, and areas vital to its interest.
3. To uphold and advance the national policies and interest of the United States.
4. To safeguard the internal security of the United States.

Secretary of Defense

The Secretary of Defense is the principal assistant to the President in all matters relating to the Department of Defense. He also serves as a member of several important councils. All functions in the Department of Defense are performed under his direction, authority, and control. He is appointed from civil life by the President, with the advise and consent of the Senate. During his absence or disability the Deputy Secretary of Defense acts for and exercises the powers of the Secretary. The Secretary of Defense has numerous assistants and advisers; however, the only ones discussed in this course are those associated with the Department of the Navy.

DEPARTMENT OF THE NAVY

The primary objectives of the Department of the Navy are to organize, train, equip, and maintain the readiness of Navy and Marine forces for the performance of military missions as directed by higher authority, and to support Navy and Marine forces including the support of such forces of other military departments which are assigned to unified or specified combatant commands. This support includes administrative, personnel, material and fiscal support, and technological support through research and development. It is composed of the executive part of the Department of the Navy, the Headquarters United States Marine Corps, the entire operating forces, and all shore (field) activities, headquarters, forces, bases, installations, activities, and functions under the control or supervision of the Secretary of the Navy. It also includes the Coast Guard when operating as a service in the Navy.

The term "Navy Department" refers to the central executive offices of the Department of the Navy located at the seat of government. It includes the following:

1. The office of the Secretary of the Navy.
2. The office of the Chief of Naval Operations and the headquarters organizations of the Marine Corps, of the Naval Material Command, and of Other Supporting Organizations.

In order to provide for its total administration, the Department of the Navy is organized into four principal parts—the Operating Forces, the Marine Corps, the Naval Material Command, and Other Supporting Organizations.

OFFICE OF THE SECRETARY OF THE NAVY

The Secretary of the Navy (SecNav) administers the Department of the Navy as one of three military departments under the Secretary of Defense and the President. As head of this Department, he is responsible for the policies and control of the Department of the Navy, including its organization, administration, operation, and efficiency. He is appointed from civil life by the President.

The Secretary of the Navy is assisted in his duties by the members of his executive administration. This includes both civilian and military assistants. The civilian executive assistants consist of the Under Secretary of the Navy, the Assistant Secretaries of the Navy, and the Special Assistant to the Secretary. The naval executive assistants consists of the Chief of Naval Operations (CNO), the Commandant of the Marine Corps, and the Commandant of the Coast Guard when the Coast Guard is operating as a service in the Navy.

Naval Professional Assistants and Staff Assistants are provided by the Naval bureaus, systems commands, boards, and staff officers.

Civilian Executive Assistants are the principal policy advisers and assistants to the Secretary on the administration of the affairs of the Department as a whole. Each assistant is authorized to act for the Secretary within his assigned area of responsibility.

14202

OFFICE OF THE CHIEF OF NAVAL OPERATIONS

The Chief of Naval Operations is the senior military officer of the Department of the Navy. He is the principal naval adviser to the President and the Secretary of the Navy on the conduct of war, and the principal naval adviser and naval executive to the Secretary of the Navy on the conduct of the activities of the Department of the Navy. He is the Navy member of the Joint Chiefs of Staff. He commands and supervises all activities of the operating forces of the Navy and is responsible for planning, maintaining the readiness of Navy forces, and determining the material support needs of the operating forces (less Fleet Marine Forces and other assigned Marine forces) including equipment, weapons, materials, supplies, facilities, and supporting services. This responsibility includes the determination of the naval characteristics of and priorities for things to be developed or procured, and the determination of the order in which ships, aircraft, weapons or weapons systems, and those facilities which directly support the operating forces of the Navy, are to be acquired, constructed, maintained, altered, repaired, and overhauled.

NOTE: Aircraft maintenance is considered part of readiness.

Naval aviation comprises a large segment of the operating forces. Aircraft is the prime element of naval aviation. The Aircraft Accounting System established by CNO is a prime informational base for management of this element. The data for this system, normally initiated by AZ's, provides CNO and other interested activities with vital information required for proper management of naval aviation.

The Chief of Naval Operations also provided the basis for the Naval Aircraft Maintenance Program (NAMP) and established policies for the assignment of maintenance responsibilities to all Navy activities concerned with naval aircraft maintenance. This program is another important management tool for naval aviation.

Three basic points in CNO's policy concerning aircraft maintenance are as follows:

1. Performance of aircraft maintenance is a responsibility of command.
2. Aircraft maintenance is administered through the military chain of command.
3. Development of maintenance functions necessary to carry out assigned maintenance duties is a responsibility of the Naval Air Systems Command (NavAirSysCom).

With the introduction of more complex types of weapons and weapons systems into the fleet, it became apparent that a new maintenance management program was needed. As a result, CNO has sponsored and directed the establishment of the Navy Maintenance and Material Management System, herein referred to as 3-M or 3-M System. The basic objective of this program is to improve the material readiness of the fleet through improved management of maintenance and material functions. This program is applicable to both ships and aircraft. Parts of the program pertaining to aviation are covered later in this training course.

The Chief of Naval Operations is assisted in the performance of his duties by several assistants. Some of these are of varying interest to the AZ and are covered briefly in the following paragraphs.

Vice Chief of Naval Operations

The Vice Chief of Naval Operations is principal adviser to CNO and performs duties of CNO during CNO's absence.

Assistant Vice Chief of Naval Operations/Director of Naval Administration

This assistant executes CNO's administrative responsibilities for the operating forces and administrative and management responsibilities for shore activities.

Deputy Chief of Naval Operations (Air)

The Deputy Chief of Naval Operations (Air) (DCNO Air) implements CNO's responsibilities for preparation and execution of programs pertaining to naval aviation and is CNO's representative in naval air operational matters involving other government and civil agencies. This deputy chief is also responsible for planning and providing for the naval aeronautical elements of the operating forces including their preparation, training, readiness for war, and their logistic support.

Deputy Chief of Naval Operations (Development)

The DCNO (Development) implements CNO's responsibilities for research, development, test,

FOSBI 14203

and evaluation programs, including coordination and direction of weapons development.

Deputy Chief of Naval Operations (Fleet Operations and Readiness)

This DCNO implements CNO's responsibilities for employment of the operating forces with the exception of the Military Sea Transport Service.

Deputy Chief of Naval Operations (Logistics)

The DCNO (Logistics) plans and provides for the necessary logistic support and material readiness of operating and inactive forces of the Navy.

Deputy Chief of Naval Operations (Plans and Policy)

The DCNO (Plans and Policy) develops and disseminates plans and policy and advises CNO on Joint Chiefs of Staff and international military matters.

Naval Inspector General

The Navy Inspector General inquires, under the direction of SecNav or CNO, into and reports upon any and all matters affecting the discipline, readiness, effectiveness, efficiency, or economy of the Department of the Navy.

NAVAL MATERIAL COMMAND

The Naval Material Command includes the Headquarters, Naval Material Command, Naval Air Systems Command, Naval Electronic Systems Command, Naval Ship Systems Command, Naval Ordnance Systems Command, Naval Supply Systems Command, Naval Facilities Engineering Command, and shore (field) activities as assigned by the Secretary of the Navy.

NOTE: A recent reorganization of the Department of the Navy established the Naval Material Command and the six systems commands. These new commands replaced the Naval Material Support Establishment which was composed of the Office of Naval Material, the Bureau of Ships, the Bureau of Supplies and Accounts, the Bureau of Yards and Docks, and the Bureau of Naval Weapons. Many directives issued by the abolished bureaus are still effective and will remain in force for some time.

Chief of Naval Material

The Chief of Naval Material, as head of the Naval Material Command, supervises and commands all functions and activities of the various systems commands. He is directly responsible to CNO for providing the material support needs of the operating forces for equipment, weapons or weapons systems, materials, facilities, and supporting services, all consistent with approved programs. He is also responsible to the Commandant of the Marine Corps for providing the material support needs of the Marine Corps which are provided by the Naval Material Command. He plans for the utilization of resources for meeting the material support needs of the operating forces.

He provides CNO and the Commandant of the Marine Corps with timely advice concerning training and technical requirements essential for the operation and maintenance by naval personnel of new equipments under development, and provides the operating forces with timely technical guidance on the operation, repair, and maintenance of all equipments and weapons or weapons systems. The Chief of Naval Material formulates and effectuates policies and methods of procurement, contracting, production of materials, and of procurement and contracting services throughout the Navy.

NAVAL SHIP SYSTEMS COMMAND.—The Naval Ship Systems Command is responsible for the design, construction, conversion, and procurement of ships, boats, and surface craft. This command coordinates with NavAirSysCom in providing adequate aircraft maintenance facilities afloat. The Naval Ship Systems Command is also responsible for the repair and maintenance of all ships and craft except those assigned to the Naval Facilities Engineering Command and to the Military Sea Transport Service. This includes prescribing the standards and procedures for the dry-docking of all vessels and technical direction of the installation, operating procedures, alterations, and maintenance of the hull, machinery, and equipment of all naval ships. The Naval Ship Systems Command is charged with the management control of all U.S. Naval Shipyards.

NAVAL SUPPLY SYSTEMS COMMAND.—The Naval Supply Systems Command formulates, promulgates, and effectuates policies and methods relative to material control throughout the Naval Establishment. This systems command administers the Navy Supply System. The

Naval Supply Systems Command exercises management control over naval supply depots, naval supply centers, Navy exchanges, and Navy commissary stores. Additional responsibilities of this systems command are discussed in chapter 7 of this training course.

NAVAL FACILITIES ENGINEERING COMMAND.—The Naval Facilities Engineering Command is responsible for design, development, construction, alteration, and cost estimates at all shore activities of the Naval Establishment. This systems command coordinates with NavAirSysCom in providing aircraft maintenance facilities at shore activities. The Naval Facilities Engineering Command also supervises the construction of private plant facilities financed with naval funds. This command is responsible for the maintenance of all buildings and structures of the Navy and for utilization of all automotive vehicles. It exercises management control over all Department of the Navy family housing and Public Works Centers.

NAVAL AIR SYSTEMS COMMAND.—The Naval Air Systems Command is responsible for the research, development, design, test, operating standards, manufacture, issue, maintenance, repair, overhaul, and material effectiveness of all naval aircraft and designated weapons systems. This responsibility includes the rework (Depot maintenance) of all Navy and Marine Corps aircraft and associated equipment.

NavAirSysCom is the coordinating authority for the Naval Aircraft Maintenance Program (NAMP) and as such accomplishes the following:

1. Provides aircraft maintenance policy guidance and technical and management review of the NAMP.
2. Establishes definitions of aircraft maintenance levels and assigns the level of maintenance to be performed by each naval activity concerned with aircraft maintenance.
3. Delineates aircraft maintenance functions and responsibilities to be performed at each maintenance level and provides the organization and procedures to be used by all activities of the Naval Establishment concerned with aircraft maintenance.
4. Assists in the development of programs to properly train and utilize aircraft maintenance personnel.
5. Provides aircraft maintenance material allowance lists together with lists of fleet and shore activities authorized, available, and required.

NavAirSysCom is charged with and responsible for the management control of certain test and development activities and all aircraft maintenance activities of the shore establishment. These activities are employed for conducting necessary research, test, and investigations to obtain suitable material for naval purposes and for supporting the functions of CNO and the operating forces.

NOTE: Management control is the exercise of executive authority and responsibility for the performance of the mission, task, and work of shore activities.

In exercising this management control the responsibility of NavAirSysCom includes mission planning; facility development and workload planning; internal organization and procedures; budgeting; accounting; and the utilization of personnel, funds, materials, and facilities. NavAirSysCom also provides appropriate coordination and application of technical direction. This technical direction is the specialized or professional service performed, or professional guidance or direction exercised through promulgation of policies and procedures in technical matters through the Navy Directives System and technical directives system.

NavAirSysCom has provided a completely centralized system for control and issue of all technical directives concerning naval aircraft and it is the only source of authority to modify, or withhold modification of, naval aircraft, except as directed by CNO or for overriding operational requirement reasons. All publications concerning the operation and maintenance of naval aircraft and associated equipment are published under the direction of NavAirSysCom.

To assist in meeting its responsibilities in the tasks of aircraft maintenance, NavAirSysCom has numerous representatives located in the field. Some of these are discussed in the following paragraphs.

Naval Air Systems Command Representatives.—Naval Air System Command Representatives (NavAirSysComReps) represent the NavAirSysCom in assigned geographic areas in liaison with elements of fleet and training commands on matters pertaining to weapons maintenance and the material support necessary for adequate fleet and training readiness. They serve to coordinate the service and material requirements of the operating and training commands with the maintenance and material support services of NavAirSysCom managed

14205

activities and supporting commercial activities. These representatives monitor the repair operations at support stations and coordinate material requirements between Aircraft Maintenance Department (AMD's) and Naval Air Rework Facilities (NARF's) at various stations. Some of their specific duties include the following:

1. Assist in preparation of aircraft rework schedules.
2. Establish engine rework schedules and requirements for support of activities performing complete repair of Navy and interservice engines.
3. Schedule component rework.
4. Assist in establishing requirements for technical publications. Review for accuracy and adequacy maintenance and overhaul publications and promote proper technical information support.
5. Coordinate requirements for ground support and special support equipment.
6. Coordinate requirements of fleet and operating activities with the engineering services of rework activities.
7. Control and distribute Change kits.

They further provide on-site guidance and technical assistance through locally assigned Field Service Representatives. These representatives assist local commands in the resolution of maintenance, material and repair problems, and in the interpretation of technical directives.

OPERATING FORCES

The operating forces are the fleets, seagoing forces, sea frontier forces, district forces, and such Navy shore activities and commands as are assigned by the Secretary of the Navy. In the final analysis, the operating forces form the naval power of the United States, and it is for their support that the rest of the Department of the Navy exists. The command, administration, and use of the operating forces are the responsibility of the CNO.

Fleet Commands

Two major subdivisions of the operating forces are the Atlantic Fleet and the Pacific Fleet. The Atlantic Fleet is under the command of the Commander in Chief, U.S. Atlantic Fleet (CINCLANTFLT), and the Pacific Fleet is under the command of the Commander in Chief U.S. Pacific Fleet (CINCPACFLT).

Each is organized for both administrative and tactical command. Tactical organization has to do with the actual deployment and utilization of ships and other units in military operations. The function of the administrative organization is to provide logistic support.

Logistics is defined as those measures involved in supplying necessary personnel, material, and equipment where and when needed. Fleet commanders are responsible for keeping the CNO, the appropriate system commands and other activities informed of operational plans which may require changes in logistic support for the operating forces. Fleet commanders establish levels of supply for overseas bases under their logistic control.

Although the fleet commanders have the responsibility of readiness within their respective areas, they have passed the responsibility of aircraft maintenance to their appropriate types commanders.

Type Commands

The Atlantic and Pacific fleets are composed of various ships and crafts classified and organized into commands by types. The type commanders report to CINCLANTFLT and CINCPACFLT, as appropriate. The type commands of primary concern to the AZ are Commander Naval Air Force, U.S. Pacific Fleet (COMNAVAIRPAC), and Commander Naval Air Force, U.S. Atlantic Fleet (COMNAVAIRLANT).

COMMANDER NAVAL AIR FORCE.—COMNAVAIRPAC and COMNAVAIRLANT are aviation type commanders exercising technical control for aeronautical material in their respective areas. These commands are sometimes referred to as "Operating Commands." Included in the functions and responsibilities of these type commands are the following:

1. Coordinate fleet aviation in their respective areas.
2. Recommend policies relating to organization, maintenance, and employment of fleet aviation.
3. Study the strategical situation and make recommendations for distribution of naval air forces and naval air shore activities.
4. Keep appropriate fleet commander advised on air operations and combat readiness of fleet aviation units.
5. Distribute aviation units in accordance with directives received from higher authority.

14205
14206

6. Initiate recommendations regarding types, military characteristics, and allowances of aircraft required.

7. Administer and allocate funds received from NavAirSysCom for maintenance and operations of assigned aircraft.

8. Allocate and distribute replacement aircraft and aircraft engines.

9. Coordinate rework schedules of aircraft, aircraft engines, and components.

These type commands are controlling custodians of naval aircraft and are responsible for maintaining assigned aircraft at the highest degree of material readiness from the time the aircraft are received in their custody until they are returned to NavAirSysCom custody at designated delivery points.

NOTE: Material readiness is defined as the condition which, achieved and maintained through careful preventive maintenance, repair, replacement, and tests, enables an aircraft, including airframe, engines, accessories, and components and also related support equipment, to fulfill the purpose for which designed.

As a NAMP coordinating authority, these operating commands are responsible for the coordination control of all aircraft upkeep or rework performed on aircraft under their controlling custody.

COMNAVAIRPAC and COMNAVAIRLANT are responsible for the supply readiness of fleet squadrons and ships tending or supporting aircraft. By outfitting directives, they provide for the initial outfitting and reoutfitting of aeronautical spares and equipment for ships. In the case of fleet squadrons, NavAirSysCom designates an outfitting air station to provide initial aeronautical organizational property and support equipment to the squadron. The type commander monitors and assists as necessary in the outfitting of fleet squadrons and provides supply assistance as the need arises.

The operating commands are also charged with the responsibility of exercising fleet (rationing) control over certain aeronautical materials as designated by the Aviation Supply Office.

The operating commands are responsible for the planned assignment and distribution of aircraft and engines to their operating units and support activities. Assignment of aircraft to individual units is made on the basis of authorized allowances established by the CNO, and the planned assignment of aircraft is determined by COMNAVAIRPAC and COMNAVAIRLANT in relation to the available aircraft inventory.

Assignments in excess of the CNO allowance are made only to meet urgent operational or training requirements. Fleet pools of aircraft and engines for backup support are also provided by this type commander. These pool levels are adjusted according to operational and replacement requirements.

Subordinate Area Commands

For administrative purposes, COMNAVAIRPAC and COMNAVAIRLANT are divided into geographical areas with a subordinate type commander for each area. These commands are designated as area subordinate commands, and they assist their type commander in carrying out directives and policies. Examples of these type activities are Commander Fleet Air (COMFAIR) Whidbey, an area subordinate command under COMNAVAIRPAC; and Commander Fleet Air (COMFAIR) Jacksonville, an area subordinate command under COMNAVAIRLANT.

These subordinate area commanders are responsible for exercising control over fleet aircraft and aviation supplies in their respective geographical areas. Some additional responsibilities and functions of these subordinate area commands are as follows:

1. Coordination of type commander aviation matters and control of aviation support to fleet air units in their assigned areas.

2. Act as the NAMP coordinating authority in their geographical areas. Act as the coordinator of administrative authority to insure that maintenance personnel, material, and facilities are used effectively and economically.

3. Administer, control, schedule, and coordinate the operations and training of assigned units.

4. Supervise and coordinate aircraft maintenance performance, including correction of aircraft technical difficulties of fleet air units, both ashore and afloat.

5. In consonance with established practices and policies, conduct investigations and render reports and recommendations on aviation matters such as material and design deficiencies experienced by operating activities; operational support problems; equipment problems and evaluations; material and equipment distribution; technical assistance requirements of fleet air units; and other general related areas.

6. Monitor the performance of aircraft maintenance logistic support functions and tasks

14207

assigned by NavAirSysCom to fleet support stations and insure that the workload is consistent with assigned functions, tasks, and fleet requirements.

7. Monitor and review for adequacy the assignment of facilities and material allowed for support of fleet activities at aviation shore activities in geographical area of cognizance.

8. Monitor the configuration control program to insure incorporation of required modifications.

9. Administer assigned technical representatives and arrange their services when requested.

10. Insure that aeronautical materials and equipment are distributed and properly controlled in order to achieve the most effective utilization.

Due to their geographical location, certain COMFAIR's have specific duties in addition to the ones previously discussed. Some of these include the following:

1. Exercise overall administration and management control over the Progressive Aircraft Rework (PAR) program and liaison team at certain Depot maintenance activities, acting as the representative of other COMFAIR's concerned and as aircraft custodian agent for the fleet squadrons.

2. Conduct administrative/material, pre- and post-deployment inspections of assigned fleet air units and such other inspections as required by higher authority or as dictated by existing circumstances and known maintenance or material conditions.

3. Supervise and coordinate the assignment, transfer, and shipment of aircraft and engines and administer pools of aircraft and engines.

COMFAIR's are directly responsible for the administration of units or commands assigned to their administrative command or operational control. They are also responsible for the administration, and operations and logistics support of other units or commands of their respective type commander operating in their areas to the extent necessary to secure uniformity, coordination, and effective liaison with shore activities within their area.

FLEET AIR WING.—A Fleet Air Wing (FAW) is a mobile combatant naval air unit consisting of a wing staff, patrol squadrons, aircraft, and other units as assigned. A FAW, as an organized operational/administrative unit, may be deployed to operate in any assigned geographical area.

The FAW Commander exercises control over assigned squadrons. He is cognizant of supply and maintenance matters and exercises supervision of units assigned regarding these functions. He is responsible to the area subordinate commander for training, efficient operation, and administration of the units under his command. This includes the responsibility for the material condition and material readiness of squadrons under his cognizance. He further insures that aircraft maintenance practices and procedures of assigned units are performed in accordance with existing directives and that maintenance quality and safety are not sacrificed to meet operational schedules.

When squadrons of the FAW are deployed, they normally come under the operational control of the area subordinate commander of the deployed area; however, administrative assignment remains with the COMFAIR or FAW at the squadron's permanent duty station.

The mission of a FAW normally includes the following:

1. Gathering and evaluating detailed and accurate information on all phases of the existing situation, which includes strategic, tactical, and logistic information.

2. Preparing plans, schedules, directives, and reports based upon such information, or in compliance with directives received from higher authority.

3. Disseminate information and directives to subordinate commanders and information and reports to higher authority.

4. Supervise and evaluate the execution of the wing commander's directives by subordinate commands.

ATTACK CARRIER AIR WING/CARRIER ANTISUBMARINE AIR GROUP.—An Attack Carrier Air Wing (CVW) consists of a wing commander and his staff; fighter, attack, and heavy attack (reconnaissance attack) squadrons; and detachments with aircraft configured for special purposes such as airborne early warning and photo reconnaissance. A Carrier Antisubmarine Air Group (CVSG) consists of a group commander and his staff; air antisubmarine and helicopter antisubmarine squadrons; and detachments with aircraft configured for special purposes.

For purposes of administrative control and assignment, the air wing/group commanders normally report to the fleet air commander in whose area the air wing/group is home ported. When embarked, the air wing/group commanders

14208

report with their embarked squadrons and detachments to the commanding officer of the carrier for operational control.

Each air wing/group has its own commander. In the absence of an assigned commander, the senior commanding officer among the squadrons assumes the responsibilities of the wing/group commander.

Air wing/group commanders have related functions and responsibilities. Some of these are as follows:

1. Supervision and coordination of the training and operations of assigned squadrons and detachments.

2. Coordination and review of material and supply functions of assigned squadrons and detachments.

3. Coordination and surveillance of maintenance performance of assigned squadrons and detachments.

4. Tactical command during wing/group operations. Each commander keeps appropriate superiors advised of the state of training and operational readiness of his wing/group.

Commanders of air wings/groups coordinate the aircraft maintenance performed by units under their cognizance to insure effective and economical use of total assigned personnel, material and facilities, and of facilities and material provided by supporting ships or stations. Wing and group commanders also coordinate planning prior to deployments to insure that necessary facilities, material, and services for the support of assigned units will be provided either by the squadron or the supporting ship or station.

The air wing/group maintenance officer is a direct representative of the air wing/group commander and as such is responsible to the commander in many matters pertaining to aircraft maintenance. Some of his primary responsibilities and functions include the following:

1. Be responsible to the wing/group commander for coordinating the proper performance of all aircraft Organizational maintenance.

2. Maintain liaison with Air, Aircraft Intermediate Maintenance, and Supply Departments.

3. Determine depth and range of organizational support equipment to be loaded aboard ship to minimize duplication and insure only items essential to support the specific deployment are placed aboard.

4. Provide timely input to the Aircraft Intermediate Maintenance Department (AIMD) officer to insure Individual Material Readiness List (IMRL) requirements are tailored to support the assigned air wing/group.

5. Determine prior to embarkation, a list by rate and rating of personnel to be temporarily assigned from squadrons and detachments to the AIMD.

6. Attend the periodic supply/maintenance conferences convened by the AIMD officer and insure squadron representation as required.

7. Monitor air wing/group squadrons and detachments to insure that active and effective quality assurance programs exist; correct maintenance department administrative procedures are employed; active corrosion prevention programs are maintained; effective foreign object damage prevention programs are established and implemented; effective maintenance training programs are being conducted; and assistance to assigned units in obtaining contractor technical services personnel.

Aviation Squadrons.—Aviation squadrons are the last link in the chain of command extending from the CNO through the various commands. The mission of aviation squadrons is to maintain assigned aircraft and associated equipment in a maximum state of readiness and to perform training and operational duties as assigned by appropriate authority. This mission is applicable to fleet aviation squadrons as well as aviation squadrons of the training commands. The responsibilities of both of these types of squadrons are closely related. The CNO assigns aircraft maintenance tasks and responsibilities to activities of the operating forces.

It is the responsibility of each squadron commanding officer to maintain assigned aeronautical material at the highest degree of operational readiness. Operational readiness is a measure of the ability of a command to carry out its assigned mission. An acceptable state of readiness permits employment of personnel and equipment with the expectation that each will perform proficiently. The necessary standards of readiness, including instructions for both tactical and technical training of personnel and for maintenance of equipment, are promulgated by higher authority. It is also the responsibility of the squadron commanding officer to insure that aircraft and personnel detailed for a particular mission are capable of performing that mission under existing conditions. This includes the responsibility for insuring that squadron personnel are trained and qualified to perform all routine and

- Determine the skill, speed, and dexterity of the applicant by having him perform such competencies as using a sewing machine, laying a pattern on fabric, and using pattern markings.

- Evaluate the applicant's knowledge and understanding of clothing construction terminology by the use of a written objective test.

An example of a performance pretest is given in Appendix A.

PROVISION OF ADEQUATE FACILITIES

Suitable training facilities may be found in the home economics department of the local school, clothing services laboratory in the area occupational center, home economics cooperative extension meeting room, community room, or factory training room. Two basic areas are needed for successfully conducting this course.

Classroom Instructional Area. A space equipped with light-weight tables and chairs, chalkboards and tackboards, projection screen, teacher's desk and filing cabinets, book shelves, storage cabinets with adjustable shelves, and a variety of audiovisual equipment.

Laboratory Area. A space equipped with both industrial and home-type machines including a lockstitch, zigzag, and buttonholer with machine benches or chairs. Machines may be borrowed or rented from local stores or garment establishments. The pressing center should include ironing boards, steam irons, sleeve board, various sized pressing hams, point presser, pounding block, needle board, seam roll, pressing cloths, distilled water, steaming machines, and small stiff brushes. Storage units for teaching materials as well as individual trainee items and equipment should also be provided.

PROMOTION OF THE COURSE

Carefully planned publicity for a variety of media is important in order to contact eligible individuals. Promotional suggestions include the following:

- Prepare and send press releases to the local newspapers several weeks in advance of the starting date for the course. The release should include the course prerequisities and content, time and place of registration, length of course, and benefits of training. See example in Appendix B.

- Prepare and distribute attractive flyers to such organizations and places as women's clubs, church groups, P.T.A. groups, and libraries. See example in Appendix C.

- Arrange for a radio and/or television interview and spot announcements. Use similar information to that given in flyer or press release.

specialized squadron maintenance functions on assigned aircraft and related equipment.

Aviation squadrons and units to which aircraft and engines are assigned are reporting custodians and as such are responsible for accounting and reporting in accordance with instructions received from higher authority. Commanding officers are responsible for maintaining current configuration of all aircraft and related equipment in their custody in accordance with NavAirSysCom and type commander directives.

Aviation squadrons are responsible for performing Organizational maintenance on assigned aircraft and support equipment. Organizational maintenance is defined as that type of work performed by aircraft squadrons and units on a day to day basis in support of its own operations. This type of maintenance includes servicing, inspections, tests, repairs, and adjustments which do not require shop facilities. This type of work is done in facilities assigned to the operating units on either a joint or an individual basis.

Standard organization has long been recognized as a sound tool of management. Through the issuance of NavAir Instruction 4700.2 (Series) a standard organization for the maintenance department of Organizational and Intermediate activities was established. This organization provides firm lines of authority from the aircraft maintenance officer to the personnel accomplishing the work.

The aircraft maintenance officer is responsible for management of the maintenance department. This is accomplished by planning and exercising proper control for the department. For detailed information on aircraft maintenance department organization, refer to Aviation Maintenance Administrationman 3 and 2.

Supporting Activities

Most naval air stations, naval auxiliary air stations, and certain naval stations are responsible for performing Intermediate maintenance. These NavAirSysCom managed shore activities are not necessarily part of the operating forces, but they are essential elements in the aircraft maintenance program. Maintenance tasks and responsibilities are assigned to these activities by NavAirSysCom.

Intermediate maintenance is defined as that type of work that is performed in centrally located facilities for the support of operating units within a designated area or at a particular base or station. This maintenance includes component repair and test work on aircraft components and equipment from the supported units. Personnel of the Intermediate Maintenance Activity (IMA) also furnish technical assistance to the supported activities.

AIRCRAFT MAINTENANCE DEPARTMENT.—Shore activities assigned the responsibility of performing Intermediate maintenance have established an Aircraft Maintenance Department (AMD) for this purpose. This AMD has the responsibility of performing Intermediate maintenance in support of station aircraft and tenant squadrons, providing Organizational maintenance facilities for tenant activities, and providing prepositioned maintenance support equipment for tenant activities.

Intermediate maintenance activities are staffed in accordance with the maintenance tasks assigned. They are manned by permanently assigned personnel and personnel temporarily assigned from the Organizational maintenance activities being supported.

AIRCRAFT INTERMEDIATE MAINTENANCE DEPARTMENT.—A recent revision in aircraft carrier organization has established the Aircraft Intermediate Maintenance Department. This department has the same basic responsibilities afloat as AMD's ashore—the accomplishment of Intermediate maintenance in support of embarked aircraft and related equipment. In addition, the AIMD is responsible for Organizational maintenance functions relating to the ship's utility aircraft.

This department is headed by the AIMD officer and consists of a nucleus of permanently assigned personnel and temporarily assigned maintenance personnel from the embarked squadrons and detachments.

Some specific responsibilities and functions of the AIMD officer include the following:

1. Administer the AIMD under the direction of the commanding officer in accordance with existing directives.
2. Manage the Intermediate maintenance effort performed in support of embarked aircraft including custody and upkeep of associated maintenance facilities and support equipment.
3. Assume Organizational maintenance responsibility for the ship's aircraft.
4. Provide and maintain aircraft maintenance facilities to support the embarked aircraft.

5. Update facility plans to accommodate deck load changes and new weapons systems.

6. Establish and update ship/wing/group personnel requirements in conjunction with the air wing/group maintenance officer to insure adequate manning for support of the Intermediate maintenance effort.

7. Maintain a current inventory of maintenance facilities and equipment and submit recomendations for changes to the Individual Material Readiness List.

8. Establish and maintain an effective training program and provide for training and licensing of personnel to operate support equipment.

9. Maintain and control a central technical library of publications for performance of Intermediate maintenance on embarked aircraft and assigned equipments.

10. Conduct maintenance/material planning conferences prior to and during deployments.

11. Assume responsibility for coordinating maintenance and security of all Intermediate and Organizational maintenance work spaces.

OPERATIONS MAINTENANCE DIVISION.—An Operations Maintenance Division (OMD) has been established in the Operations Department of Naval shore activities from which naval aircraft are operated. This OMD is responsible for performing Organizational maintenance on all assigned aircraft. Under special circumstances, they perform additional maintenance services within their capability.

Prior to the establishment of the OMD, the AMD had the responsibility of maintaining assigned station aircraft. This newer concept permits the AMD to more completely carry out its mission of support.

NAVAL AIR REWORK FACILITY.—Naval Air Rework Facilities (NARF's) are located at certain air stations in the U.S. NARF's are responsible for performing Depot maintenance.

Depot maintenance is defined as that type of work that must be done in an industrial type facility. These facilities may be either military or commercial. This type of maintenance includes overhaul and major repair and modification of aircraft, components, and related equipment. It also includes the manufacture of designated aeronautical parts and the manufacture of kits for the accomplishment of aircraft and equipment modification. The support rendered by NARF's is servicewide.

NAVY MAINTENANCE AND MATERIAL MANAGEMENT (3-M) SYSTEM

The Navy Maintenance and Material Management System is the Navy's answer to an evolutionary process which has brought weapons systems to higher complexity and national defense dollars to lower purchasing power. The most efficient management of materials and manpower must be exercised if maximum readiness is to be achieved. The cost to maintain an acceptable state of readiness is of prime importance. In reality, readiness and cost considerations complement each other. By analyzing maintenance cost and devising techniques to reduce cost wherever it is economically feasible, many unnecessary actions can be minimized, if not entirely eliminated. Thus, by doing away with that which is not absolutely required, effort can be concentrated on that which is required—increased readiness. The end objective of this system is to insure the highest state of aircraft readiness and reliability at the lowest cost in men, money, and materials. This system insures that maintenance personnel, equipment, and facilities are utilized to the fullest extent in actual maintenance performance.

BASIC PRINCIPLES

With the implementation of the 3-M System it was known that naval organizational and command relationships are evolutionary and subject to continued change. Names and composition of organizations can be expected to change as they have in the past. However, this system is based on certain basic principles which can survive changes in organizational and command relationships. Some of these principles are discussed in the following pragraphs.

Levels of Maintenance

The three levels of maintenance, Organizational, Intermediate, and Depot, as prescribed by the Secretary of Defense, are the basic divisions within the entire spectrum of aviation maintenance upon which this management system is founded.

Lowest Level Maintenance

The requirement of this basic principle is that all aircraft maintenance be performed

S1 14211

at the lowest possible level. The distribution and the availability of maintenance equipment and facilities determine and govern the performance of maintenance at specific levels. Commands and support agencies are responsible for insuring that the distribution of equipment and facilities is continually reviewed for the purpose of increasing the amount of maintenance performed at the lowest level consistent with available skills and personnel.

Management by Exception

This basic principle is fundamental to the entire management system. It means that actions or incidents which vary noticeably from certain standards or norms are singled out or "excepted" from the whole for special management attention. For example, if certain aircraft models consistently fail to meet established material standards, they would be singled out for special study and corrective action. Likewise, if certain systems or components within an aircraft continually fail and consume abnormal numbers of maintenance manhours or parts, these would also be exception items. The principle of management by exception is not new and is particularly adaptable to aviation maintenance management through the use of modern machine data processing techniques.

Material Control and
Supply Support

Another basic principle upon which this system is based is that maintenance personnel be utilized primarily in actual maintenance work. This system provides for personnel other than assigned maintenance personnel to supply the worker with required parts and materials. The mechanic or technician does not become involved in part chasing, but devotes his time to actual maintenance performance.

COMPONENT PARTS

The 3-M System includes two broad areas, a Planned Maintenance System (PMS) and a Maintenance Data Collection System (MDCS). These areas are discussed briefly in the following paragraphs.

Planned Maintenance System

The PMS pertains to preventive rather than corrective maintenance. The Periodic Maintenance Requirements Manual (PMRM) and the Maintenance Requirements Cards (MRC's) tell what inspections have to be performed; when they should be performed; how they should be performed; what skills, tools, and special equipment are required to perform them; safety precautions to be observed; and the sequence in which individual inspection actions should be accomplished. The PMRM and MRC's provide this information in a form readily accessible and understandable by supervisors as well as by the workers. The PMS for aircraft and related aeronautical equipment is under the cognizance of NavAirSysCom.

Maintenance Data Collection System

The MDCS is a maintenance and material management control and information system which includes maintenance data reporting, among other things. The primary purpose of data collection in this system is to insure that basic data generated by maintenance personnel is recorded once, and only once, and that the system (not the maintenance activity) thereafter provides information to all who have need for it.

Under this system, there are four categories of data recorded by maintenance personnel and collected for machine processing. In order to be machine processed, most of this data is recorded in code form. The four categories of data are manhour data, maintenance data, aircraft statistical data, and aviation maintenance support equipment statistical data.

MANHOUR DATA.—Data on the total utilization of personnel assigned to maintenance activities is recorded and collected, using the exception principle. Whenever personnel assigned to a maintenance activity are utilized for any purpose other than that for which assigned, they record the amount of time so spent on cards which are collected daily and machine processed.

As long as all personnel are utilized 100 percent of the time in their primary maintenance assignments, no manhour cards are submitted. Manhour data provides a measure of exception from the theoretically perfectly manned, organized, and managed maintenance organization. Together with the actual production manhours recorded on other documents, the manhour accounting system provides a valuable tool for measuring the effectiveness of maintenance personnel utilization, the validity of maintenance personnel assignments, and the

1181. 1212

validity of the structure of the maintenance organization.

MAINTENANCE DATA.—This category of data includes the widest range and most complex types of information involved in the MDCS. This data is recorded on five different collection forms. Examples of information recorded on these forms are discrepancy correction, aircraft inspections, component repair, and technical directive compliance.

AIRCRAFT STATISTICAL DATA.—This management system prescribes the use of an Equipment Statistical Data Card for recording aircraft flight, readiness, and inventory change data. These data are recorded on an as-occurring basis and are machine processed. These data provide all the information needed to produce the reports required in aircraft accounting as well as readiness and utilization information for managers to help measure their effectiveness.

AVIATION MAINTENANCE SUPPORT EQUIPMENT STATISTICAL DATA.—Aviation maintenance support equipment statistical data is collected on selected items of support equipment in a similar manner as in aircraft statistical data; that is, the Aviation Maintenance Support Equipment Data Card is used to record inventory changes, status code changes, not operationally ready time by reason, and utilization. These data are collected and machine processed and provide maintenance managers valuable information required for efficient management of aviation maintenance support equipment resources.

ORGANIZATION PRINCIPLES AND MANAGEMENT FUNCTIONS

The specific objective of aircraft maintenance is to keep all aircraft and related equipment in a serviceable status. Although this might appear to be a simple objective, it raises several problems. Gone are the days when a mechanic repaired an aircraft with a pot of glue and bailing wire. In fact, maintenance activities are finding it increasingly difficult to keep pace with the consequently improved performance of Navy Equipment. Further, management and supervisory personnel in maintenance activities must give increased attention to technological progress in order that their activities may be properly geared to meet present needs and be adequately prepared for further advances.

The Navy, like any other branch of the armed services, consists of people, equipment, and facilities. Although it is basic to the Navy's program to make provisions for adequate and balanced equipment and facilities, one of the most pressing problems is the acquisition, training, management, and retention of suitable personnel. Little good would be accomplished if the Navy had the best equipment and facilities in the world yet lacked enough thoroughly trained personnel to operate and manage these activities effectively.

For example, it has been estimated that during World War II personnel of the Armed Forces used mechanical equipment to not more than one-third of its potential effectiveness because personnel did not have the necessary training and experience to do better. Of course, all-out war makes it necessary to get men to the "line" as fast as possible; however, it is easy to see that there would have been less loss and waste during World War II if there had been better training and more experience.

For the most part, the equipment of World War II was simple compared with present day weapons and weapon systems. Some of today's aircraft are so complex that they require as much maintenance as the public utilities of a small city. Likewise, the average length of experience and the amount of training required to operate and maintain Navy equipment and to conduct Navy activities are increasing constantly. Thus, to put the success of technological efforts in operation, managers must have capable individuals, must train them thoroughly, and must use established principles in managing the entire aircraft maintenance program.

Prior to entering into a discussion of maintenance management functions or principles, it is important that the AZ have a knowledge of certain principles of organization. These organization principles are important to management and must be applied in order to properly manage a maintenance activity. Some organization principles are discussed in the following sections.

PRINCIPLES OF ORGANIZATION

Organization principles are like the principles of physics or chemistry in that they are truths upon which other truths are founded. They are guideposts and beacons to the manager and are not guesswork or opinion. They are the basis for management policies, procedures, rules, and decisions. Therefore, any policy

1491 1013

violating the principles of management is doomed to failure.

Organization exists when two or more persons combine their actions to achieve a common objective. Such combined actions are very numerous. For example, the actions vary from the simple type, such as man and wife acting as a family unit, to the many individual actions involved in the operation of a big business such as the Navy. Experience has shown that many factors are common to an organizational structure. These common factors must be present in order for any unit to be considered well organized, and these factors are called principles of sound organization.

History bears witness to the practicability of the art of organizing. Institutions and states have become great through its application or have decayed because the new management was unable to continue practicing this art. Critical study shows that when principles of organization were properly employed, the resulting organization accomplished its mission more effectively. On the other hand, an organization which violated these principles has usually proved unsound and inefficient.

There are four fundamental principles of sound organization—unity of command, span of control, logical assignment, and delegation of authority.

Unity of Command

Unity of command means that ultimate control of actions toward the determined objective of the organization at any one level is vested in one individual for a group of workers. There should be several parallel groups, each with its own supervisor at each level except the very top; otherwise, the organizational breakdown is not needed. In simple terms, this means that there should be only one boss at each controlling level. Acceptance of this principle provides for the establishment of a definite chain of command and for effective control of subordinates.

In order that an individual can carry out his job as a leader, manager, or supervisor, it is absolutely necessary that he know to whom he reports. Otherwise, he would not know from whom he receives orders or to whom he reports his results. As basic as this idea may seem, it is often ignored or misunderstood, and these relationships are frequently unsatisfactory to a degree that efficiency is seriously impaired. It is a known fact that when personnel are confused the result is a loss of efficiency.

The supervisor must know whom he directs. He must know who is working for him and who is aiding him in accomplishing a particular job. Moreover, a detailed knowledge of whom he directs enables a supervisor to assign responsibility and to delegate authority.

Span of Control

The principle of span of control means that there is a limit to the number of individuals within an organization that a supervisor can effectively control. In all supervisory positions there are three limiting factors which must be carefully considered in establishing procedures which can be effectively controlled. These factors are the number of personnel under one supervisor, the space or distance factor, and the time factor.

In considering the span of control numbers, experience has developed the concept that a supervisor should manage not less than three nor more than seven subordinates doing different jobs. If he supervises less than three, full advantage of his own capabilities has not been made. If he supervises more than seven, he may not be managing efficiently because there is too great a strain on his energy and ability. This concept has been accepted by most authorities on management and is based upon actual observation of management practices in many fields of human endeavor.

If the activities which are to be supervised require frequent personal contact, then the question of the accessibility of these activities must be considered in organization and locating them. The matter of distance from the supervisor has considerable bearing on how well he is able to do his job. If the activities are spread out over a large base, the time required to travel to these activities is excessive, and the transportation required is wasteful. When the distance between the supervisor and the activities is increased to such an extent that he must waste energy and resources, his effectiveness is reduced.

On the other hand, it may be just as unwise to locate a subordinate too close to the supervisor as it is to locate him too far away. Having a subordinate too close may result in oversupervision. It is a natural tendency for a supervisor to oversupervise those personnel who are located nearest to him. This

14214

oversupervision means interference with the work of the subordinate and frequently results in stifling him to such an extent that he becomes a person who does only what he is told to do and nothing more. Locating him too far away results in undersupervision, and the subordinate begins to operate independently to such a degree that the influence of the supervisor becomes incidental.

The optimum distance between the supervisor and the subordinate should be that distance which minimizes both oversupervision and undersupervision. The determination of this optimum distance becomes a matter of good judgment rather than measurement.

Every supervisor's job should consist of four principal types of work—routine, regular, special, and creative. There is a certain amount of routine work in every supervisory position which should be performed insofar as possible by subordinates. Regular work primarily consists of such duties as normal supervision of activities and subordinates and those duties which can be performed only by the supervisor. Special work is that which is assigned to the supervisor by his superiors or initiated by himself and which is not related to his regular work. Creative work is that which is done to improve the quality or quantity of routine work and is the work which assures progress in an organization.

Hence, the principle of span of control time implies that the supervisor should control his use of time in order to effect accomplishment of all work which he is assigned. Routine work should be kept to an absolute minimum and should be assigned as far as practicable to subordinates. Regular work should be carefully scheduled. If a number of activities are involved, each one should be alloted time proportional to its relative importance. Special work is a recurring factor in the military, and time should be provided for it. Creative work is also necessary on all jobs, and time must be set aside for its accomplishment.

A proper balance of the three factors—numbers, distance, and time—is necessary in any supervisory position if the principle of span of control is to be satisfied. A desirable state of control can be assured only when a supervisor balances all of these factors with respect to his situation. An equally important principle is that of assigning a person to the job he can do best.

Logical Assignment

The principle of logical assignment means that all functions required to accomplish the mission of the organization should be logically grouped and that all individuals should be assigned to these groupings in accordance with their capabilities.

The principle of logical assignment has been applied to the organization of the Navy. The Chief of Naval Operations is charged specifically with the operation and the development of all phases of naval warfare. To discharge this responsibility, the CNO has organized the Navy so that many functions of his overall mission have been assigned as responsibilities to specific individuals and organizations. The operating functions derived from his mission have been analyzed and grouped logically under the major Navy commands. Similarly, his major staff functions have been analyzed and grouped logically within his headquarters and under the major divisions of personnel, development, material, operations, etc.

There are two phases in the application of this principle—the organizing phase and the personnel assignment phase. In the organizing phase the principle is applied by the logical assignment of functions and relationships within the structural framework of the organization. In the personnel assignment phase the principle is applied through the assignment of personnel, based on their abilities and capabilities to perform the logically grouped functions of the organization.

In the final analysis, the application of the principle of logical assignment provides for the following:

1. An assurance of proper assignment of the "right man on the right job." This is extremely important when it is realized that many people have claimed incorrect assignment and improper classification. Consequently, their morale and efficiency are influenced by their grievances.
2. A higher efficiency and speeding up of training by limiting the range of work.
3. The placing of responsibility, giving credit for an accomplishment, and eliminating a failure.

In addition to logical assignments, a further step requires the granting of authority needed by a person to do the job well.

Delegation of Authority

Delegation of authority means that authority given to a subordinate should be proportionate with his assigned organizational responsibilities. It is the application of this principle which motivates an organization. Delegation of authority might be compared to the electrical power emanating from a central generating plant which sets otherwise idle motors to work.

Delegation of authority applies to all types of organizations and to all levels of management. It becomes more important as the scope and degree of responsibility of the individual increases.

Authority is derived from several sources. First, there is the authority represented by force of character and personality. Some people are marked, even in a gathering of strangers, as persons commanding attention or with an "air or authority." Second, there is the authority due to technical knowledge. The possessor of such knowledge is normally accepted as an "authority on a certain subject." Lastly, there is the authority due to position. A certain authority is inherent in the two stars of a rear admiral; and similarly, a certain authority attends the position of a maintenance officer.

A supervisor delegates to a subordinate the authority to do a certain thing. This delegation of authority should be commensurate with the assigned responsibility of the subordinate. Normally, this authority is limited by directive or custom. Authority must always be delegated; otherwise, assigned responsibility has no logical basis. A supervisor should not, of course, hold a subordinate responsible for the accomplishment of a job that the subordinate has not been given adequate authority to accomplish. Delegation of authority, then, is a means with which the supervisor makes use of the assistance of others and motivates their efforts.

These various organization principles apply to a maintenance activity as well as other types of organizations. All of these principles must be considered by maintenance managers and supervisors in order to achieve the desired objective of a particular activity. Some of the principles are taken care of in Organizational and Intermediate level maintenance activities by following established organization procedures outlined in NavAir Instruction 4700.2 (Series). Others must be applied by local level managers and supervisors. The AZ supervisor should strive to apply these principles in his area of responsibility in order to contribute his part to the accomplishment of the overall unit or activity mission.

MANAGEMENT FUNCTIONS

A good manager is one who uses the available resources to the fullest extent in order to accomplish an objective in the most economical manner. When applied to aircraft maintenance, a maintenance manager uses the available resources (facilities, personnel, funds, equipment, etc.) to maintain the highest percent of aircraft operational readiness. In accomplishing this task, a manager or supervisor performs five separate and distinct jobs—planning, organizing, directing, coordinating, and controlling. These are discussed in the following sections.

Planning

There are no prerequisites or technical skills for management planning, since planning is essentially thinking through each job. It includes a realization that no operation is too small to benefit from planning. Planning is foresight directed toward the manipulation of future developments in order that they will serve the purpose toward which the organization is directed.

A manager or supervisor who has neither a general plan nor a plan for each day's work is shirking his job of supervision. The histories of the rise and fall of big and little businesses and even stories of the family picnic have proved that the planned activity is always the most successful.

Successful planning requires at least four steps. First, it requires the ability to visualize not only the end purpose of an operation or the finished job but also the whole procedure involved in reaching that purpose.

Second, the planner must have a background of experience related to the task he is about to plan. Planning implies a comparison of the projected undertaking with past jobs of similar nature.

Third, considering the diversified activities involved, the planner must take measures to insure that these activities will be coordinated. This involves a careful inventory of material, equipment, and personnel requirements.

Finally, the planner must be able to check his plans in terms of their probable strength and weakness.

The good supervisor should begin his planning by deciding upon a major objective. Next, he should break this major objective down into the minor tasks involved. He can then arrange the smaller jobs in a chronological order of their accomplishment. Naturally, these decisions require the gathering of certain facts in a systematic way.

Organizing

The principle of organization must be applied to the supervisor's unit or department. A sound structure can be formed by constantly recalling the purpose of the organization. Organizational planning should be objective rather than personal. It involves three steps which should be followed by the planner—job analysis, the organizational chart, and assignment of personnel.

Directing

The directing function is the "spark plug" of supervision. By using this function, the supervisor gets the organizational process started. His orders actuate the services determined by planning and established by organization. Giving orders is all too often interpreted as the main function of a supervisor; however, an order should not be given without planning, and it cannot be successful without organization, coordination, control, and a knowledge of the art of handling people.

The supervisor should keep the following principles of directing in mind:

1. Base no decisions on doubtful material.
2. Gather all of the facts and make sure they are correct.
3. Never make a decision that might tend to lower the worker's respect for him.
4. Decide in terms of the human element.

To sum up, the directing function involves three steps: (1) assignment of each worker to a specific area or responsibility, (2) making orders clear and following up assignments, and (3) giving specific orders, whether verbal or written.

Coordinating

Coordinating, as applied to maintenance functions means to function harmoniously. Those acts of the manager which are necessary to integrate the functions within his unit and between his unit and other units or organizations are known as the functions of coordination. Thus, a unit is considered coordinated if its integration promotes the unit's functions without impairing the operation of other units.

Primarily, coordination is a balancing agent. By coordinating the work properly, the supervisor can have the right part at the right place at the right time as well as the right man to install the part. Good coordination requires that the efforts of a group of individuals must blend together as smoothly as the thousands of parts in an efficiently operating aircraft engine.

People are not born with a talent for coordination. The efficient supervisor learns to increase his production by using definite methods to coordinate the work of his unit. The root of coordination is good planning, but additional techniques must also be used. Records and reports designed to reveal information are invaluable. Organization charts and routing schedules are tools for planning coordinated effort. Finally, conferences are a check on how well individuals are actually working together.

Another function that the supervisor must perform is one of control. He must know whether his unit and the individuals in it are operating up to a standard and whether they are meeting their deadline or quotas. To insure that they do this calls for skillful use of the controlling function, which is exercised through a number of procedures.

Controlling

The devices set up by higher echelons are the basic controls. These must be supplemented by local controls specifically designed for a particular unit. Statistical controls collect and make available needed information, and manhour controls serve to keep a record of time spent on the job. All of these controls must be set up and administered if a supervisor is to exercise his control function wisely.

Basically, control is that portion of management which is concerned with inspecting, testing, guiding, and limiting. Control has a direct effect on all functions of management. Obviously the supervisor must know how well his unit is working. His control system is the only means he has of determining whether his workers are doing an effective job. Control is often misinterpreted. It does not mean spying on individuals. Control is the objective inspecting and testing of the end product that is produced.

14217

Chapter 3

SUPERVISION AND ADMINISTRATION

To most personnel an assignment to a supervisory position is a welcome challenge. Most personnel like the feeling of added prestige, authority over others, and the feeling of progress that goes with the assignment. However, the AZ must realize that the job of a supervisor is not as easy as it may have seemed when viewed from any other position.

Every day the supervisor is confronted with many problems and situations requiring immediate action. If the supervisor knows his duties and responsibilities, knows his personnel, knows the different tasks and their priorities, then he may be able to cope with the supervisory job. However, if he does not know these things, troubles may begin to multiply at an alarming rate.

In addition to the supervisory functions, senior AZ's perform many administrative and clerical type duties in support of the Naval Aircraft Maintenance Program. This chapter discusses some of the general duties and responsibilities of the AZ supervisor and some administrative functions he performs.

Prior to entering into a discussion of supervision objectives and the duties of a supervisor, it is important that the AZ clearly understand the meaning of the words supervision and supervisor.

Supervision can be defined as the act of guiding, directing, overseeing, evaluating, and controlling the activities of others in the accomplishment of an objective. Supervision is the total of all activities performed by persons in a supervisory capacity which help achieve the desired objective.

Supervisor can be defined as the person who practices supervision or one who is responsible for and directs the work of others. The supervisor is usually the middleman between the workers and the policymakers. From this position the supervisor represents the policymakers to the workers and the workers to the policymakers.

ROLE OF THE SUPERVISOR

Most of the duties of senior AZ's are performed in an office. A great deal of the time expended is spent performing supervisory duties. The job of supervising the operation of an office is a many-sided task. Some of the techniques will have been learned through past experience. Others will have to be learned during the actual supervision of the office. Still other techniques may be learned from self-study and technical publications.

Supervisors set in motion the plans, schedules, and policies of their superiors. They are primarily concerned with seeing that the job is done, not necessarily performing the work themselves. Supervisors must know their personnel, assign them work to be done, train them to do the best job possible, direct them through the performance of the work, and assume responsibility for seeing that the job is done right. The role of a supervisor requires leadership, commonsense, and respect.

The effective supervisor, faced with a difficult descision, assembles pertinent facts, policies, and procedures; develops and evaluates possible alternatives; objectively selects the best alternative, and when necessary, consults his own supervisor; and then proceeds with the required action. Facing problems squarely promotes the success of an organization. Making sound decisions gains for the supervisor the respect and confidence of superiors and subordinates alike.

The supervisor's duties consist chiefly of planning, direction, and control. Planning is the process by which the supervisor establishes

14218

"who will do what, when." Direction involves the " doing." Control refers to the process of checking "what was done" against "what was planned."

The importance of the supervisor to the success of the Navy cannot be overemphasized. The supervisors are the people who fit into the organization between policymaking and policy execution. They create the climatic characteristics of an efficient working unit. The cooperation, loyalty, and capabilities of the personnel "who see that the job is done" provides the foundation on which a successful organization is built.

SUPERVISION OBJECTIVES

Supervision objectives may vary from one task to another; however, there are certain supervisory factors which are standard in almost any situation. A specific list of these factors can be made only when referring to a specific position. The following list contains some typical objectives common to AZ supervisors.

1. Correct personnel assignment; that is getting the right person on the job at the right time.
2. Maintaining quality and quantity of work.
3. Keeping accurate records and accurate reports preparation.
4. Planning and scheduling work.
5. Giving orders and directions.
6. Checking and inspecting completed tasks.
7. Using materials economically.
8. Proper care and use of office machines.
9. Training personnel.
10. Promoting teamwork.
11. Maintaining discipline.
12. Keeping morale high.
13. Maintaining liaison with other work centers in the organization.
14. Maintaining good housekeeping.

By analyzing these typical objectives it can be found that they may be grouped into three broad categories. Thus, the objectives of office supervision are as follows:

1. To operate with maximum efficiency.
2. To operate with minimum expense and waste.
3. To operate free from interruption and difficulty.

While these are primary objectives of office supervision, it is well for the AZ who may be assigned these duties to keep in mind the fact that this new assignment is important for personal reasons. It affords an excellent opportunity to gain practical experience toward eventual promotion to AZCS and AZCM.

Operation With Maximum Efficiency

The operational efficiency of an office is dependent to a large extent upon how conveniently the desks and work areas are arranged. The new office supervisor will want to make an evaluation of the existing office layout to assure the most efficient arrangement possible.

The supervisor by virtue of his position has authority over personnel in his charge. He tells them what to do, when to do it, and if necessary how to do it. This authority alone is not enough to get maximum effectiveness from the crew. A supervisor should know the limitations and capabilities of assigned personnel in order to get the most work out of them. If at all possible, a supervisor should assign a well qualified worker to do a certain job and add to the team other individuals who are less qualified but who are professionally ready for advanced on-the-job training.

The supervisor must anticipate the eventual loss of experienced personnel through transfers, discharges, etc., and offset this by the establishment of an effective and continuing training program. In addition to raising the skill level of the office, the training program will insure that personnel, otherwise qualified, will be ready for the advancement examinations.

A knowledge of the principles of manhour accounting is necessary in the efficient utilization of the manpower available. The supervisor should schedule his workload in such a way that planned absences of key workers will not unduly interrupt the daily routine. When scheduling the workload, the supervisor should keep in mind the skill level required for the various tasks and assign individuals to jobs in such a way that the work will still progress if any worker is unexpectedly absent.

Analyzing the discussion thus far would indicate that an efficient office is one whereby the supervisor practices balanced supervision. This means paying proper attention to each phase of the supervisor's responsibility. Production should not be emphasized at the expense of quality workmanship or personnel training. By the same token, the supervisor should not become so concerned with the human element that

14219 USSF

SECTION II

The State Course of Study

The State course of study is so arranged that it may be adapted to a variety of local situations. Also, the course is planned to provide training for a number of different jobs, thus encouraging individuals with varying levels of ability to enroll. The course is organized into units which can be combined to meet individual interests and abilities. Trainees may advance from garment ripper to dressmaker or may leave at different levels with salable skills. Those who complete the entire course may find employment in a variety of jobs.

OVERVIEW OF THE COURSE

The design of the State course of study is to provide instructional units to help prepare individuals to become skilled workers in the area of garment alterations. Jobs for which training is planned include garment ripper, women's clothing finisher, alteration seamstress, alteration tailor's helper, women's garment fitter, and dressmaker. A description of each job is presented in the chart entitled, Job Titles and Descriptions, found on the following page.

The State course of study consists of six units or learning areas and are listed below.

Unit 1 - Use and Care of Fabrics
Unit 2 - Selection, Use, and Care of Sewing Equipment
Unit 3 - Techniques of Sewing
  Topic 1 - Pressing Techniques
  Topic 2 - Construction Techniques
  Topic 3 - Alteration Techniques
  Topic 4 - Repair Techniques
Unit 4 - Elements and Principles of Design
Unit 5 - Preparation for Employment
Unit 6 - Management of a Garment Alteration Business

Each unit and topic contains competencies, a motivating procedure, learning experiences, instructional materials, and instructor references. Content for each unit or topic is implied in the suggested learning experiences. An explanation of each part is given below.

Competencies. Specific skills needed to become proficient in the learning area are listed. These skills may be measured by using a variety of techniques such as observation, a rating scale, or a check list.

Motivating Procedure. A method for gaining the student's interest and pointing up the importance of the material to be learned is suggested. This procedure should create a curiosity and a desire to go further into the topic presented.

production is neglected. Keeping up with the routine paperwork will prevent its accumulation to the extent that very long periods will have to be devoted to catching up, at the expense of other important tasks. The supervisor should always strive to put the proper emphasis on each phase of responsibility to promote office efficiency.

Operation With Minimum Expense and Waste

The AZ as an office supervisor is responsible for the efficient and economical administration of the office to which assigned. This responsibility includes the ordering, accounting for, and proper utilization of supplies and office equipment. All forms of wastefulness should be avoided by insuring that office supplies and equipment are used for only those purposes for which they are intended. Senior AZ's assigned office supervisory billets must impress upon assigned office personnel the need for being thrifty. There are many ways to economize, and the AZ office supervisor should always be on the alert to point out these ways to less experienced individuals.

Sometimes it is difficult for the AZ supervisor to be as cost conscious as he should, because he is not actually handling the money involved. However, a misdirected effort, wasted time, wasted material, etc., represent additional cost and affect the efficiency of an office as well as the efficiency of the overall activity.

Methods of avoiding waste and unnecessary expense should be included in the training program.

Operation Free From Interruption and Difficulty

The meeting of this objective depends largely upon the extent to which the office, office equipment, and files are maintained. Also, the skill level and training of assigned personnel must be considered in meeting this objective. Office machines of the proper type and quantity (and in good working order) and an up-to-date file of applicable instructions, notices, publications, etc., are all important factors which contributes to an efficient job completion with minimum interruptions or difficulties.

The office functions may be smoothed by the judicious delegation of authority to individuals next in seniority to the supervisor. The delegation of authority does not relieve the supervisor of the final responsibility for work accomplished. It is primarily a means of relieving the supervisor of details. A supervisor who allows himself to become too involved with details loses effectiveness as a supervisor. If the office can run smoothly and efficiently under normal conditions without the personal directions and efforts of the supervisor (for a reasonable period of time) then delegation of authority to other members of the crew has been done properly.

PLANNING OFFICE ARRANGEMENT

The average Chief or First Class Aviation Maintenance Administrationman may never have the opportunity of planning the layout of the maintenance office or production control office in a new facility. In almost every case, the new supervisor will take charge of an already functioning office or else, upon deployment or movement to a new base, the supervisor with assigned personnel will usually be assigned to spaces already basically equipped for offices. In either case, a reevaluation of the office's layout is indicated.

Purpose of the Office

A basic consideration in planning an office layout is the purpose of the office. When more than one office space is available, the supervisor must decide which offices will occupy the spaces and, if necessary, which will have to share space. Of two spaces identical in size, one may, for example, be completely unacceptable for a production control office due to its location or the shape of the area. A production control office should be centrally located in the maintenance department, readily accessible to all divisions and branches, and of adequate size to accommodate all required functions. Consideration must be given to the lighting conditions as adequate lighting is a prerequisite to many office functions. Also, bulkhead space must be considered if status boards or other displays are to be mounted. These two factors must also be considered in arranging the furniture and office equipment.

Arrangement

After the decision of what offices are to occupy what spaces or areas within a space comes the arrangement of furniture and office equipment.

The arrangement of the office furnishings should be made on the basis of utility rather than appearance. Moving an item of equipment into a corner may greatly improve the appearance of the office but at the same time reduce the efficiency of personnel using the equipment. For example, if there is only one adding machine in the office and its use is required by several people it should be located in such a position that all concerned have access to it, and not situated in an out-of-the-way corner. A good rule to follow is to locate equipment where it can be used by the greatest number of people with a minimum of effort in the least amount of time.

The office layout should have provisions for an information or bulletin board upon which may be posted maintenance posters, instructions and notices, plan-of-the-day, and such other information as is appropriate from time to time. The bulletin board should be located in a prominent place in the office, preferable near the entrance where everyone assigned will have to pass at one time or another during the day. Material on the bulletin board should be changed frequently, expired notices promptly removed, the current plan-of-the-day posted early, and other posters and material rotated periodically. If the same material is presented in the same format every day, it will not be long before the personnel begin to ignore the bulletin board, and purposes for having it are defeated. New arrangements are noticed and interest is stimulated with variety and changes.

SCHEDULING AND ASSIGNMENT OF WORKLOADS

Among the most important factors with which the senior AZ is concerned as an office supervisor are the assignment and accomplishment of the workload. This objective is the satisfactory completion of assigned tasks in a reasonable length of time, utilizing available personnel and materials as efficiently as possible. In order to achieve this objective, the supervisor must become skilled in estimating the amount of time to allow for the completion of each task. To be able to estimate effectively, the supervisor must have a knowledge of each job as well as a knowledge of the capabilities of each assigned person. The supervisor must realize the importance of assigning both qualified and unqualified personnel to the jobs, consistent with the training program and the priority placed upon the work to be accomplished. Allowances must be made for planned interruptions. When scheduling the work, the supervisor should also allow for unplanned interruptions and not operate on so tight a schedule that minor unplanned interruptions completely disrupt the schedule.

Most office tasks for which the AZ supervisor is responsible are of such a nature that the quality and quantity of personnel assigned to do them directly affect the time that will be required for completion.

Probably the most important single aid in estimating time and personnel requirements for the completion of tasks is a job plan. Within an office or production work center job planning is one of the most important functions of the supervisor. The job plan need not be an elaborate, complicated masterpiece. Instead, it should be simple with a certain amount of flexibility. In order to be of the most benefit it should be realistic.

Proper planning and assignment of the workload saves time, reduces cost, and makes the job easier and more pleasant for the entire crew. It can eliminate friction, jealousy, and confusion, and free the supervisor from detail work. Proper planning expedites the work and eliminates "bottlenecking," and also makes the supervisor's job easier.

The supervisor should start the day by checking over the work to be done. He should plan for maximum utilization of manpower and material. Periodically during the day, checks should be made to insure that things are progressing as planned. At the day's close, the supervisor should check on progress and prepare for the next working day as this is the best way to begin estimating time and personnel requirements.

After job completion, in order to assure that the job is indeed satisfactorily completed, the supervisor should inspect the finished work.

Personnel Work Assignments

Work assignments should be rotated so that all personnel will have an opportunity to develop skills in all phases of the AZ work. When assignments are rotated, the work becomes more

interesting for the personnel. Another reason for rotating work assignments is that if one highly skilled person performs all the work of a certain type, the supervisor and the office would be at a great disadvantage in the event this person is transferred from the office. Less experienced personnel should be assigned to work with the skilled in order to become proficient in accomplishing a particular task.

Strikers should be assigned to various tasks so that they will acquire experience on all kinds of jobs. A special consideration for the assignment of strikers to jobs is that they should be assigned progressively to jobs of ascending levels of difficulty. On some complicated jobs, a striker may be a useful assistant and understand what is being accomplished if basic tasks have been mastered.

Allowing for Planned Interruptions

During a normal workday, occasions will arise when personnel have to leave their working spaces for one reason or another, thereby delaying the completion of the scheduled work. Some delays can be anticipated; some cannot. Among those which can be anticipated are training lectures, immunization schedules, rating examinations, meals, and watches or other military duties.

Before making personnel work assignments, the supervisor should determine what delays can be anticipated. It may be possible to arrange assignments so that work interruptions are held to a minimum. When estimating the completion time of a task, the supervisor should allow for these predictable delays.

WORK SIMPLIFICATION

Work simplification is a common sense, systematic method of identifying and analyzing work problems, developing solutions, and installing improvements. In order to achieve maximum efficiency each supervisor must do his part to improve the work situation and achieve maximum manpower utilization. This implies that the greatest possible use of all resources available be made in order to help accomplish an activity's mission. Work simplification is a tool which can be utilized effectively in the accomplishment of this goal. Work simplification might be considered as human ingenuity applied to the work situation. It is the organized use of common sense and creative thinking in the solution of work problems.

If all men had believed that there could be no better way of doing things, we might still be throwing rocks at game for our food and traveling from place to place on foot. Progress in these fields was not made in a single step but in a series of improvements. These changes occurred slowly over the centuries, growing out of a multitude of small improvements.

The supervisor who lives day to day, satisfied that what he did yesterday is good enough for tomorrow, will, in most cases, leave his job no better from having held it. He leaves nothing significant for other personnel to follow him in his job, and he becomes lost in the shuffle of men who are content with merely living and dying.

The majority of improvements in our world did not come by accident; rather, they came as a result of man's ingenuity, growing out of his sense of imperfection and his constant search for improvement. When an improvement is made, no matter how small, it marks its discoverer as a person of imagination with a real and active interest in his work.

The supervisor who believes in and practices work simplification procedures can look with pride upon his contributions or those of people who work with him. This means that the supervisor should never cease to search for improvement and must encourage his workers to try to improve jobs over which he has control.

The supervisor should always watch for areas where work can be simplified. Work simplification pays immediate dividends by increasing both production quality and quantity. It allows the supervisor to meet work schedules more easily and reduces waste by producing with less effort, increases savings in time and manhours, and thus reduces cost of operation. Work methods improvement aids in establishing standard procedures. These standard procedures aid in training both old and new workers, since most workers are easier to train, and learning is much easier if standard practices are used.

An example of work simplification that is widely used in maintenance activities is a reports tickler file. The tickler file contains information on each report concerning the kind of report required, form or format to be used, due date, address of the office or command to which it is sent, etc. Although the governing directive should be consulted when preparing a report, a properly used reports

ISS 14222

tickler file simplifies and assists in the preparation and timely submission of required reports.

Work simplification should be considered when arranging the furniture and equipment in an office. If possible, the files should be located near the personnel that use them the most as this would save time and steps. In a like manner, the aircraft status board should be located where it is easily viewed without having to disrupt someone from a desk job in order to see it.

It is true that with good leadership personnel can be encouraged to work to the limit of their physical endurance but unless their efforts are used wisely, the most critical resources—manpower—is being wasted. In the final analysis, it is not how hard personnel work but how much quality work is accomplished that matters. Therefore, to help achieve maximum results with minimum expenditure of human effort, the supervisor should always strive to use established work simplification techniques.

Work simplification permits continuous evaluation by analyzing existing methods and procedures with a view toward improving them. There is always a better way of performing a task by using streamlined methods, improved tools, better working conditions, or shorter procedures. However, these better methods are not always apparent. Work simplification should be directed at all work situations where physical effort is expended.

Techniques

There are many techniques for improving work methods. For the most part, these techniques are adaptable to an office or any part of an organization as well as a whole activity. Five of the principal techniques which have been successfully applied to work operations are discussed briefly in the following paragraphs. All of these techniques require the construction, completion, and use of lists, charts, flow diagrams, etc., in order to study and analyze specific areas.

WORK DISTRIBUTION ANALYSIS.—Work distribution analysis is a technique used to analyze objectively the division of work in an office or organization. In order to obtain the most effective distribution of work, it is necessary for the supervisor to have an overall view of the organization and its operations. The supervisor must clearly understand the work that is being done and be able to see the relationship between the overall operation and the individual work units as well as the contribution that each person makes to the work of the whole organization.

Distribution of work is an important factor in efficient use of manpower. Time and effort are saved if related duties are performed by the same person. Thoughtful matching of assignments and qualifications is important so that personnel are not struggling with work that is too hard for them or wasting their time on tasks that might be performed by a less skilled person. Another consideration is distribution of workload to avoid inequalities, since these result in bottlenecks and other inefficiencies.

Work distribution analysis requires that a Task List be completed for each person whose work is being studied. This list contains, in simple statements, tasks the worker performs regularly and the average number of hours spent on each task per week. Next, a Function List is prepared which lists each function performed by the office or unit. Each task reported on the Task List must be related to a specific function. A Work Distribution Chart is prepared from the data collected on the Task List and Function List. This chart presents the work performed in the existing organization under current operating conditions. The chart is then studied and analyzed to find answers to questions such as the following:

1. What functions take the most time?
2. Is there misdirected effort?
3. Are skills being used properly?
4. Are personnel doing too many unrelated tasks?
5. Are tasks spread too thinly?
6. Is work distributed evenly?

A careful study and analysis of the work distribution chart should assist in achieving the following results:

1. Elimination of unnecessary tasks.
2. Reduction of time spent on relatively unimportant functions.
3. Elimination of duplication and overlapping of work.
4. Better balance of workloads.
5. Combination of related tasks.
6. Realistic estimate of personnel needs.
7. Better utilization of skills.
8. Reallocation of misassigned personnel.

WORK COUNT ANALYSIS.—Work count analysis supplements the work distribution analysis and is a technique for determining the

volume of work in terms of measurable units. Information obtained by counting or measuring the work provides a basis for improving methods and procedures, adjusting work assignments, evaluating performance, and eliminating bottlenecks. Such information is useful in assigning and scheduling work to insure that the workload is equitably distributed among all personnel.

Items of work counted should be definite and comparable. For instance, letters typed might be counted whether long or short, but the typing of aircraft status reports, Work Requests, or other items of this nature should not be included with the letters. Items counted should also be representative of work usually performed. Only those should be counted that clarify methods employed. Counting may take place where the work comes into the office or organization, where a decision is made or action is taken, where a process is completed, or where long storage occurs.

Work count information can be used to accomplish the following:

1. Establish how long it takes to do a given piece of work.
2. Indicate whether the volume of a certain piece of work is sufficient to warrant specialization.
3. Show whether work is distributed evenly among workers.
4. Point out bottlenecks where work piles up.
5. Indicate whether the office or organization is adequately manned, overmanned, or undermanned.
6. Stimulate interest of personnel by providing comparisons of one person's work with that of another or with his own record during a different counting period.

FLOW PROCESS ANALYSIS.—Flow process analysis is a technique for analyzing flow and sequence of operations. The purpose of this analysis is to reduce time and distances in a process by eliminating, combining, and changing the sequence of steps in the flow of work. This work simplification technique is particularly applicable to an office where paperwork flow is to be studied.

The principal tool of this technique is the construction of a flow process chart which provides a clear and detailed picture of the flow of work. Recording each step in a procedure helps to identify duplication of effort, backtracking, and other obstacles to the smooth, efficient flow of work.

MOTION ANALYSIS.—Motion analysis is a technique for making maximum use of physical motions. It is a method of studying the motions of individuals in performing their various tasks.

Work distribution and flow process analyses are directed toward improving the division and flow of work. Motion analysis deals with how an individual performs his tasks. It seeks to learn whether the workers are doing their work with minimum fatigue, loss of time, and waste of effort. Improvements are effected by rearrangement of materials and work area and by proper use of equipment. Motion analysis is particularly applicable to repetitive clerical operations.

The simplest way of gathering data for motion analysis is for the supervisor to watch his personnel at work and note useless motions. Motion analysis should result in the elimination of wasteful motions and consequent loss of work time, reduction of fatigue by lessening the amount of physical effort required to complete a task, and increase the efficiency of personnel.

LAYOUT ANALYSIS.—Layout analysis is a procedure designed to lead to better utilization of space, personnel, and equipment. A study of the layout of a working area can provide useful information for improving the work of individuals, distribution of the workload, and flow of work from one person to another. Its purpose is to determine what space is needed for the operations to be performed and how the available space may be used most effectively. Besides shortening and simplifying motions, it should produce working conditions that are as comfortable and personally satisfactory to the workers as possible consistent with efficient and economical operation. This type of analysis is especially useful when planning office arrangement.

The layout chart is the principal tool of this type of analysis. This chart consists of a floor plan of the work space, showing doors, windows, electrical outlets, etc. All features that restrict usable space should be included. Items of office furniture should be added and the flow of work indicated.

The following principles should be kept in mind when studying an office layout chart:

1. Units and individuals having the most frequent contacts should be located near each other.
2. Personnel having heavy in and out traffic should be located near entrances.
3. Arrangement of equipment and facilities should allow for effective supervision.
4. Layout should provide for maintenance of proper security precautions.

14224

5. Filing cabinets and records should be conveniently accessible to those who use them.
6. Personnel using the same equipment should be grouped together.
7. Office space allocation should be consistent with working conditions.
8. Desks should face in the same direction and should not face the windows.

INSTALLATION OF IMPROVEMENTS.—Briefly speaking, work simplification means improving methods of doing work or finding a better way. Improved methods usually involve eliminating unnecessary parts of the job, combining and rearranging other parts of the job, and simplifying the necessary parts of the job. By improving methods personnel are able to do better work, with less effort, in less time, without hurrying, with greater safety, and with lower cost. The pattern for achieving the benefits of work simplification is as follows:

1. Select the job to be improved.
2. Break down the job in detail.
3. Question the job and each detail of the job.
4. Develop the new method.
5. Apply and install the new method.

The fact that changes are recommended as a result of a work simplification study does not always mean that these changes will or can be made immediately. There are several reasons why a change that many regard as an improvement may be slow in being adopted.

Most any change will draw objections from a certain number of persons. There are two general types of reasons for these objections. First, many people regard a recommended change as a criticism of the way they have been doing their work and therefore resent it. Most of this type of objection can be avoided if those who will be affected by the change can participate in some degree in the analysis so that the whole enterprise becomes a group activity. If this is not possible, at least a clear explanation should be made regarding reason for the change. Emphasis should be on future advantages rather than criticism of old methods. Secondly, most people have a natural dislike to changing established work habits. If advantages of the new method are clearly explained, this resistance lessens considerably.

Before making any changes it is well to consider carefully all likely effects, for sometimes unforeseen effects may cancel out the beneficial aspects of the change. It is important, for instance, when new equipment or facilities are contemplated, to be sure that advantages of the new installations will outweigh cost. Indirect effects of change upon other equipment or conditions should also be considered.

Effects upon interorganizational relationships should also be taken into account. If work procedures are speeded up in one phase of an operation only to create a bottleneck in another, there will be little or no improvement.

MANHOUR ACCOUNTING

The effective employment of personnel resources is an important function of maintenance management. Manpower to the supervisor is perhaps the most important resource that must be conserved in order to have effective management of a maintenance activity. It is a resource which can be misused and wasted, even by a supervisor with the best of intentions, and the misuse or waste can remain undetected for indefinite periods. However, when some system is used that provides an accounting of manhours and the manner in which they were expended, it becomes apparent whether this resource is being properly utilized. The manhour accounting system (used by Navy maintenance activities) provides an automatic feedback of data which enables the supervisor to maintain records, monitor utilization, forecast production capabilities, and perform the necessary analytical studies required of a good supervisor. The analytical studies pinpoint areas where improvement is needed, and these weak areas should be changed to reflect improved personnel utilization, thus, better efficiency.

Accounting of all manhours expended in a maintenance organization includes not only maintenance manhours but all time spent on other activities as well. There are two types or classes of time which are accounted for—exception time and labor hours. Exception time is reported on Manhour Accounting Cards and labor hours are reported on maintenance data collection system source documents. The manhour accounting system provides accurate, uniform accounting. Effective manpower planning and programing depends upon information available only from a complete manhour accounting system.

Maintenance activities within the Navy use the exception time accounting principle. This accounting procedure makes it possible to assign each individual to a specific type of duty (such as direct labor, supervision, maintenance

225

training, etc.) and report only the manhours expended (excepted) outside the assigned duty. In essence, the exception time accounting permits the establishment of "accounts" for each work center; each "account" covers the total manhours assigned to the work center by a specific labor code. As long as all personnel are utilized 100 percent of the time in their primary maintenance assignments, no manhour cards are submitted. Whenever personnel assigned to a maintenance activity are utilized for any purpose other than that for which assigned, the amount of time so spent is recorded on cards which are collected daily and machine processed by data services. By operating with only exceptions to adjust this account, the amount of administrative paperwork is reduced.

Operation of the exception time system may be compared to the operation of a bank. Each work center establishes an account (based on the total available manhours) at the beginning of each reporting period, using manhours instead of dollars. As the work center supervisor submits exception cards (on a daily basis), the hours are added to or subtracted from this bank balance by a computer. If a supervisor borrows labor from another work center or has his own personnel work overtime, the available manhours should be increased; in these cases the exception time is added to the account.

Exception time is subtracted from the account in any cases where the worker is not producing according to the exact capacity for which his manhours are "banked." If a worker is loaned to another work center or if he is serving in some other capacity, he is not serving in the capacity for which his manhours were to be expended. This time would therefore be excepted and is subtracted from the balance. At regular intervals the supervisor is furnished reports or "statements," which reflect how well the account is being balanced.

As previously stated, the Manhour Accounting Card is the source document used to report exceptions. One of these cards is initiated each time a person excepts from normal for a period in excess of three-tenths of an hour. The card is completed at the end of the exception. Daily, these cards are machine processed by data services and the accumulated data is provided to maintenance managers and supervisors in the form of reports.

The work center supervisor is the "heart" of the manhour accounting system. He is charged with the management of the system within his work center. This includes screening of all cards for accuracy, submission of all cards, accuracy of rosters, etc. To meet this responsibility the work center supervisor must make sure that each worker thoroughly understands the system and individually gives an accurate accounting of his time.

MANHOUR ACCOUNTING REPORTS

To be of value to management, the manhour data accumulated through the submission of manhour accounting cards must be presented in a logical sequence and usable format. This is accomplished by data services through the use of data processing machines. The resulting listings and summaries are distributed to the maintenance activities as manhour accounting reports. The reports are designed to provide maintenance managers and supervisors with the information required to indicate general trends as well as to present information of a specific nature.

The formats for the standard daily and monthly manhour accounting reports are common. The essential difference between the reports is the amount of data included in each and the manner in which this data is listed or summarized.

There are four standard reports used in the manhour accounting system. These are discussed in the following paragraphs.

Work Center Daily Labor Listing (MHA 1)

This report is designed for the work center supervisor and is a detailed listing, by work center, of all Manhour Accounting Cards submitted the preceding day. It is a mandatory report and is available to the work center supervisors not later than 0800 hours of the first working day following the date of receipt of the manhour accounting cards by data services.

The work center supervisor can use this report to check the validity of cards submitted the previous day, and any erroneous entries can be corrected by forwarding appropriate correction cards. Deviations from the normal, that is, unwarranted loss of personnel to nonproductive labor codes, excessive absence manhours, etc., can be immediately identified and necessary action taken. The loss of direct labor personnel to indirect or other categories of labor

can be monitored on a day-to-day basis. Overtime expenditures can be monitored to determine if any adjustment of the work schedule is indicated.

Work Center Monthly Labor Utilization Report (MHA 2)

This report is also designed for the work center supervisor. It is a summary, by work center, of all labor transactions for the month. It is a mandatory report and is available to the work center supervisors not later than 0800 hours of the third working day following the end of the reporting period.

This report provides the work center supervisor with information as to how his personnel have been employed during the month by showing the amount of manhours expended in each type of labor. The distribution of manhours expended by the work center during the month can be compared to previous or established labor utilization rates to determine if the work center is operating within desired limits. In combination with past statistics, labor utilization trends can be plotted and examined. Factors having an adverse effect on the productivity of the work center may be recognized and cause appropriate remedial action. Manhour expenditures may indicate a need for manning adjustments and loss of personnel to functions outside the work center may be identified.

Branch/Division Monthly Labor Utilization Report (MHA 3)

This is a nonmandatory report and is a summary, by branch or division, of all labor transactions for the month. If used, it provides the branch or division supervisors with the same basic information as the MHA 2 report. The only difference is that the information is applied to a branch or division instead of individual work centers.

Organization Monthly Labor Utilization Report (MHA 4)

This is a mandatory report and is intended for the maintenance officer or comparable managers. It is made available to the applicable recipients not later than 0800 hours of the fourth working day following the end of the reporting period. Some of its uses are as follows:

1. Identification of total number assigned to, and utilized in, each labor code during the month.
2. Identification of total overtime manhours expended in each labor code during the month.
3. Surveillance of broad categories of labor to insure the organization is employing its manpower resources to best advantage.
4. Isolation of potential trouble areas such as low utilization of direct labor personnel, excessive amounts of manhours lost to nonproductive labor, abnormal duty or nonduty absence rates, and similar variations from normal.
5. Comparison of productive and supervisor manhour expenditures to insure overmanagement is not prevalent.
6. Data contained in the report may serve as the basis for reallocation of manpower.
7. Consolidated manhour information for submission to higher authority is available when required.

Special Reports

There may be times when some specific data, not furnished by one of the standard reports, is needed. In such cases, special reporting requirements may be coordinated with the local data services through the analysis division. Special reports should be requested only if the information requested is needed and is not available in any of the standard reports as this may place hardships on data services due to the increased workload.

NAVAL CORRESPONDENCE

Official correspondence in the Navy includes all recorded communications sent or received by a person in the Navy in the execution of the duties of his office. Besides letters, correspondence includes such things as messages transmitted by teletypewriter, radio, telegraph, or automatic tape equipment. It also includes endorsements attached to letters or memos.

Outgoing correspondence is originated for requesting or furnishing information. It follows that a legitimate need for the information must exist. A request for information should be prepared only after the need for the information has been clearly established and after exhausting possible local sources. In general, correspondence furnishing information depends

GGSAL 14227

upon the needs of other activities and cannot be controlled locally.

Two very good references (in pamphlet form) are available to assist in writing or checking correspondence. One is the Navy Correspondence Manual, SecNav Instruction 5216.5 (Series), which is the standard guide for all types of Navy correspondence. The other is Plain Letters, an aid in composing simple, easily read letters.

In this section, the word "letters" is used as an inclusive term for naval letters, speedletters, and messages.

TRANSMISSION METHODS

After the requirement has been established, the means of communicating must be selected. The normal possibilities are messages, speedletters, naval letters, or a regular business letter.

A naval message is an official communication in brief form transmitted by rapid means such as radio and is used only when the information is of an urgent nature and must be transmitted rapidly. Convenience of preparation and ease of releasing naval messages at most activities leads to abuses of the communications system. Unless specifically directed by higher authority, routine reports are not sent by message. Other messages should be controlled carefully and continuously to reduce traffic as much as possible.

Speedletters may be used for any routine communications. They are more informal than regular letters, and may be written either in message format or regular form. If they are of an urgent nature, requiring immediate action, they should be stamped or marked URGENT in the upper right corner. Replies to speedletters may be made on the same copy received if the originator has supplied an extra copy and space permits.

Naval letters are used for regular routine correspondence, particularly for more formal communications. The format is rigidly observed, as shown in the Navy Correspondence Manual. The makeup normally follows a pattern of introducing the subject and references in the first paragraph, discussing the subject in such detail as is necessary in the second paragraph, and concluding with any request or special comments in the third. The discussion may cover more than one paragraph if the subject matter is such that it can be understood better when handled in segments.

Business letters are used for corresponding with individuals or businesses outside the Navy who are not familiar with the naval letter.

CLASSIFICATION

Proper security classification of correspondence is a serious problem in the Navy, largely through overclassification. The writer should make certain that classification, if assigned, is justified by a genuine need. The classification should be indicated on the rough draft, and the draft handled as required by that classification.

There are no simple rules for security. One just has to digest the various policy directives and then apply commonsense. To overclassify correspondence is to saddle its purpose with administrative shackles resulting in too few people being informed too slowly. Correspondence does not have to be classified according to classification of references unless it reveals a significant part of their content. Sometimes it is convenient to put the really meaty stuff in a letter (or its enclosure), and then explain that the enclosure (or letters) may be treated as unclassified if separated.

Each piece of correspondence should be assigned the lowest classification consistent with the proper protection of the defense information contained in it. The classifying authority should resist the natural tendency to overemphasize the importance of his work by assigning unnecessary classification categories.

Correspondence and documents should be classified according to their own content and not necessarily according to their relationship to other documents. This procedure is particularly important when documents are part of a series. Various paragraphs or sections of a single document may be classified differently, with the whole document bearing the highest classification contained in it.

One part of the classifying process which warrants continuing attention is marking for downgrading or declassification. Provisions for automatic future downgrading or declassification of the document should be carefully considered at the time of the initial assignment of classification. The originator determines, whenever possible, the conditions under which the document can be downgraded or declassified and marks this plainly on the document.

The details of classification assignment and markings are described in the Department of

the Navy Security Manual for Classified Information, OpNav Instruction 5510.1 (Series). All personnel should be familiar with this manual and especially those who have the authority to classify. It should be consulted when in doubt as to the proper assignment of classification to correspondence.

PREPARATION

Several types of written material are originated and produced in an office, among which are letters, directives, and reports. The manner in which production is handled reflects the supervisory ability and attention to duty of the AZ managing the office.

Aircraft maintenance departments receive large quantities of correspondence. Some of the more common types are directives outlining aircraft maintenance policies and procedures, naval letters requesting and furnishing procedural information, and letters and memorandums assigning duties and individual responsibilities.

Since AZ's are regularly assigned duties as office supervisors, they need skill in the preparation of correspondence. Outgoing correspondence is normally drafted by senior petty officers or officers of the maintenance department. There may be times when the AZ will be expected to compose letters from the briefest of notes or even from oral instructions. Under these circumstances, skill in drafting correspondence is required.

Some correspondence originated by aircraft maintenance departments is of a recurring nature and is relatively standard in content. This may include such correspondence as periodic and special reports to higher authority. Correspondence of this nature is normally simple to draft, and file copies of previous correspondence may be used as a guide.

When assigned to a billet requiring the preparation of correspondence, it is necessary to consult local command instructions outlining the details pertaining to the preparation of official correspondence in that command. The Navy Correspondence Manual is the basic instruction concerning preparation of official correspondence and should be consulted to solve problems that arise in correspondence preparation.

Naval letters, speedletters, and messages are related in that they are correspondence used to convey information from one point to another. The major differences in the three are the format in which prepared and the speed and method of transmission.

There are several factors to be considered in preparing correspondence. This section is designed to assist in achieving efficient production by discussing some of the various phases of producing written material.

It is suggested that the chapter on Maintenance Office Administration in Aviation Maintenance Administrationman 3 & 2 be reviewed with this section.

Planning

A more effective letter will be produced if some time is given to planning prior to beginning to write. A plan of some kind is necessary to insure that everything intended will be included in a clear and orderly arrangement. Whether the writer outlines the letter completely, makes brief notes, or carries his plan in mind will depend upon the length of the letter and his own methods of working.

One of the surest ways to write unacceptable letters is to fail to lay the proper groundwork. Laying the groundwork cannot be done without putting thought into what is to be produced. Laborious as it may seem, one must break out references and assure himself that he has all the required information. Then, all the solutions should be considered in the light of this groundwork and the best chosen.

Correspondence which is worth writing must be based on clear thinking, must be carefully prepared, and must be written in clear, concise form. Otherwise, it is usually better left unwritten. In reply to any letter, it is imperative that all questions raised be answered as directly and accurately as possible. This demands thought and research.

Purpose

Planning cannot begin without a clear knowledge of purpose, so it must be understood exactly what the letter is intended to accomplish. Preparing a statement on the subject of the letter will help in clarifying the purpose and will furnish guidelines about what must be included and what should be omitted.

It is possible for a letter to deal with more than one subject, but normally this is not advisable unless the subjects are very closely

JOB TITLES AND DESCRIPTIONS	
JOB TITLE	JOB DESCRIPTION
Garment Ripper, Alteration; Hand Sewer (D.O.T. 782.884)†	Cuts or rips stitches from sections of garments to be altered by following chalk or pin markings and using a razor blade, scissors, or a seam ripper.
Women's Clothing Finisher (D.O.T. 785.381)†	Prepares garments for show window or floor by pressing and sewing on labels. Makes minor repairs such as tightening snaps and replacing buttons.
Seamstress, Alteration Woman, Women's Garment Alterer, Alteration Finisher (D.O.T. 785.381; 782.884)†	Alters women's ready-to-wear garments as instructed. Rips stitches from darts and seams to be altered and then sews by machine or hand the ripped sections of garment to customer's measurements. Presses fabric articles, using steam iron. Repairs fabric articles, replaces parts, and lengthens or shortens garments.
Alteration Tailor's Helper (D.O.T. 785.281)†	Assists tailor in a variety of duties performed in the alteration of tailored garments. Rips stitches from seams and darts to be altered and then sews by machine or hand the ripped sections of garment to customer's measurements. Replaces pockets in men's clothing and cuffs on pants. Presses garments using a steam iron or tailor's pressing equipment.
Women's Garment Fitter, Ladies' Ready-to-Wear Fitter, Dress and Coat Fitter, Women's Garment Alteration Fitter (D.O.T. 785.381)†	Fits women's ready-to-wear garments on customers. Studies garment worn by customer to determine alterations required. Pins altering folds at seams or darts to arrive at desired fit. Measures and marks hem to specified length. Records required alterations and instructions concerning alterations on tag and attaches to garment. May supervise the person who rips and resews garment.
Dressmaker, Ladies' Tailor (D.O.T. 785.381; 785.361)†	Makes, alters, and repairs women's garments such as coats, dresses, skirts according to a pattern or customer's specifications by using hand or machine sewing. Presses articles with a steam iron to smooth seams and remove wrinkles.

†D.O.T. numbers are found in the *Dictionary of Occupational Titles, Volume I-Definitions of Titles;* 3d ed. Washington, D. C. U.S. Government Printing Office. 1965.

1420

related. A reply on one subject may be prepared in hours, whereas days or weeks may elapse before an appropriate answer can be made on another subject. If both questions are asked in the same original letter, confusion is likely to result. One department of the recipient activity may prepare the reply on one subject and a different department on another. Even though more than one letter may have to be written to an activity the same day, it is better to do so than combine unrelated matters.

Seven different types of letters that are most commonly used are as follows:

1. Request for permission or authorization to act.
2. Request that action be taken.
3. Request for information.
4. Letter supplying information or instructions not requested.
5. Reply to a request for permission or authorization to act.
6. Reply to a request that action be taken.
7. Reply to a request for information.

While not every letter drafted will fall into one of these categories, the categories will serve as examples of how to analyze and plan a letter. For instance, when the purpose is to request something, the writer must be certain that the request is definitely and clearly stated. Usually, there should be a statement as to why the request is being made and any additional explanation or suggestions that are required or appropriate.

When a letter is written in reply to one received, the receipt is acknowledged, not only by citing the letter as reference, but in the body of the reply. If a request has been made, the most important thing in the reply is a clear statement as to whether the request is granted or denied. Further explanation, limitations, or suggestions should be included as appropriate. Long letters frequently need a summarizing statement as the final paragraph.

Organization of Contents

The order in which the various parts of the letter are arranged should be planned with the reader in mind. A letter of request, for instance, may begin with the request itself, followed by an explanation of why the request is made. Sometimes it may be clearer to the reader if the letter begins with a discussion of the situation and leads up to the request. A letter of reply frequently begins by acknowledging the letter received.

Four important factors to be considered in letter organization are as follows:

1. The body of the letter should be a succession of units.
2. These units should be arranged in what seems the most satisfactory order.
3. Complete each unit before moving to the next.
4. Maintain continuity by providing transition from one unit to another.

In letters of average length, each important unit may be one paragraph, although there is no rule about this. For example, an explanation of reasons why something should be done may take more than one paragraph. Some letters, on the other hand, may be so simple that one paragraph is enough for the entire body. Just as each letter has a subject, so each paragraph covers a topic or subtopic. Each paragraph has its own orderly structure, so that one idea leads naturally to another and one paragraph leads to another.

Principles of Good Style

Most people agree that a good letter is clear, concise, direct, courteous, and suited to its purpose. The major problems confronting the writer is how to achieve these qualities. Some progress toward clarity will be made if an orderly plan for the letter has been produced. The rest will depend on the language chosen for carrying out the plan.

The simplest unit of language is, of course, the individual word. Combined in meaningful groups, words become sentences, which in turn are placed in orderly sequence to become paragraphs. Each of these units requires attention if good style is to be achieved.

CHOICE OF WORDS.—Choosing the right words is a long step toward good style. The best words are those that are precise in meaning, suited to the intended reader, and as short, simple, and direct as possible.

Words used in letterwriting should be exact in their meaning. They can miss the mark of exactness in several ways. One of the most obvious is choice of the wrong one from two that sound or look alike. Quite often the words differ not only in their spelling but also in their meaning. The dictionary should be consulted in all cases when there is doubt as to the correct word to use. As the writer becomes better acquainted with meanings, he will find ways of remembering them. Among words

that are related or similar in meaning, the discriminating writer usually will find one that suits his purpose better than another.

In choosing words, always keep in mind the person for whom the letter is intended. For example, when preparing a letter to a senior command, "Your attention is invited" is used rather than "Attention is directed."

A directive addressed to all hands is written in language all can understand. This does not necessarily mean that only one-syllable words are used, but it does mean that the words chosen are meaningful and understandable by all hands.

The use of long words merely for the sake of sounding more important or more dignified should be avoided. Such an attempt usually results only in sounding showy, stuffy, and hard to understand.

While short, simple words are generally best, not everything can be said in words of one syllable. Sometimes the exactly right words to express something might require the use of long words. In this case it would be a mistake to substitute a less accurate term just for the sake of using shorter words. For instance, even if there were shorter words to replace the term "electronic data processing," it is doubtful that they would convey the same meaning.

Using technical language always requires consideration of the reader. If he is a specialist in the technical field under discussion, technical terms may be used freely, but for anyone else, the terms should be carefully chosen, and some may need to be defined. This is true even for well educated readers, since no one can be familiar with all kinds of technical language.

The fault in some writing is not only that long words have been used where short ones would do, but also that more words are used than necessary. Most senior AZ's will probably have the occasion to review another person's letterwriting. While performing this task, the AZ should be careful when making minor changes or additions, for in striving to make the language more precise, he may cause the passage to mean something the writer did not intend.

MISPLACED WORDS.—One of the most common faults in sentence structure is the misplacement of words, phrases, or clauses. This kind of error occasionally trips up even those whose English is otherwise very good. The result is always confusing and often ridiculous.

The problem of misplacement usually arises with modifiers. These misplaced modifiers are commonly called dangling modifiers. Modifiers should be positioned close to the words that they modify, because otherwise, they may seem to modify something else. Haste, carelessness, or lack of understanding of grammar may cause a writer to use a construction without thinking exactly what it is supposed to modify. This kind of error is fairly common in using participles and other adjectives or with adverbial modifiers.

A frequently misplaced word is "only." The following example shows how, by moving this one word around in a sentence, the meaning is entirely changed.

Only he could read the strange dialect. (Nobody else could.)

He could only read the strange dialect. (He could not write or speak it.)

He could read only the strange dialect. (He could read nothing else.)

He could read the only strange dialect. (Only one dialect was strange, and he could read it.)

It should be kept in mind that there are many other words, which if improperly used, can completely change the intended meaning of a sentence.

SENTENCE STRUCTURE.—To be effective, sentences should be grammatically correct. Also, the various types of sentences should be well chosen and effectively combined, with an eye to clarity, emphasis, and interest.

The faults discussed in this section, although fairly obvious, are common enough that it will be worthwhile to review them.

A frequent fault in grammar among inexperienced writers is the incomplete sentence or sentence fragment. By this is meant a sentence that does not contain the two necessary parts, a subject and a verb. It is possible for the subject to be understood rather than stated, but in this case it should be clearly implied. Often an incomplete sentence results from failure to recognize that a modifying phrase or clause is really part of the preceding sentence.

Do not be misled by the fact that some literary men of high reputation deliberately turn out incomplete sentences at times. It is true that fractured sentences may occasionally produce the exact effect desired, but the writer should be sure he knows why they are being used and that they are suitable to what is being written. For example, the fragment "Bigger and better airplanes!" may have a place in some kinds of writing. In official correspondence

this kind of structure should rarely be used.

Beginning a sentence with "but" or another connective is regarded by many as incorrect, largely because the connective standing first seems to indicate a fragment. This is one rule that may occassionally be ignored if by doing so one achieves a more effective statement. It should not be done often or the effect will be lost.

Another common error in sentence structure is the punctuation of two or more sentences as if they were one. These are known as run-on sentences. Usually this occurs with sentences that are closely related in thought. Often a run-on sentence is the result not only of faulty punctuation but also of failure to think the construction through and recognize the relationships of the various ideas.

Sentences may be grammatically correct and still not be as effective as possible, in which case the fault is described as one of style. Style in writing, like style in dress, is a personal thing—a matter of taste and knowing how to combine. A writer's style may be clear or confusing, concise or wordy, lively or dull.

No one can tell a writer exactly how to achieve a suitable and pleasing style, but there are some general rules which, if understood and applied judiciously, will get him started in the right direction.

As in the case of vocabulary, style should, first of all, suit its purpose. A style that might be quite suitable for a human interest story in the newspaper might be inappropriate for an official letter.

Another rule, also mentioned in connection with choice of words, is that simplicity is usually best. One of the classic examples of simplicity, Lincoln's Gettysburg Address, can be clearly understood by children in the lower elementary grades yet retains its appeal to the most sophisticated ear.

Sentence length affects style in several ways. Generally, short sentences are simpler and easier to understand than long ones. Usually too, short sentences are brighter; long sentences, more dignified; and unless the writer is careful, more inclined to dullness. The average length of sentences in any piece of writing should be adjusted to the subject matter, the reader, and the writer's purpose.

Interest and emphasis can often be improved by variation in sentence length. For instance, in a paragraph in which most sentences are of average or no more than average length, an occasional short sentence may serve to stress an important point or to break the pace agreeably.

Sentences that are too short are inclined to produce a choppy effect, the sound of which is not particularly pleasing. Sometimes these sentences should be combined into a longer one that will not only sound better but will also be more meaningful because the relation of the several statements to each other has been clarified.

A periodic sentence is one in which a period cannot be placed before the last word without cutting off a vital part of the sentence. In other words, the sentence usually ends with the verb or with some other vital word rather than a word, phrase, or clause, that merely adds information. A restrictive modifier—one that is necessary to complete the meaning of what has gone before—may stand last, occasionally, in a periodic sentence, but not a nonrestrictive modifier. If the sentence ends with a nonrestrictive word, phrase, or clause, the sentence is called loose.

In the following example, a periodic sentence (1) has been changed into a loose sentence (2), note that in the transformation the emphasis has shifted enough to change the meaning somewhat. The loose sentence implies that selling activities need not comply with local laws except under these circumstances.

1. Whenever small arms and ammunition not required to be demilitarized under this instruction are offered for public sale, the selling activity will comply with the applicable local laws.

2. Selling activities will comply with applicable local laws whenever small arms and ammunition not required to be demilitarized under this instruction are offered for public sale.

Periodic sentences are more deliberately constructed and therefore more formal than loose sentences. The latter are more characteristic of informal conversation. Neither one can be said to be right or wrong. Whether one or the other is used will depend partly on which is more effective in getting across the meaning of the particular sentence. In an official letter or directive, periodic sentences probably should predominate, but there is no need to try to make every sentence periodic. Some loose sentences are desirable to keep the style from sounding stilted.

PARAGRAPHING.— A well written paragraph has unity, which means that the ideas it contains are closely related and are arranged to develop a single topic or subtopic of the general subject. In modern official letterwriting, the tendency is toward short paragraphs, for the sake of readability. This requires not only that unnecessary verbiage be pared away but also that the subject matter be very carefully organized and subdivided.

A fairly long paragraph is frequently made more effective if introduced by a topic sentence. Such a sentence makes a general statement that is developed in greater detail in the remainder of the paragraph.

A topic sentence need not stand at the beginning of a paragraph; in fact, it is possible to have a well written paragraph with a topic sentence in the middle or at the end. In naval correspondence, the topic sentence in the middle of the paragraph is less likely to be used. If placed at the end, it becomes a summary, a very useful device for pulling the paragraph together and leaving a strong final effect. The summary at the end of a paragraph is not used extensively in naval letters and directives. A summary paragraph for an entire letter is sometimes appropriate.

A well organized paragraph has its various ideas introduced in an orderly sequence. This sequence may be place order, chronological order, logical order, or order of emphasis. The purpose of all is the same—to lead the reader along the path one wishes him to take with a minimum of backtracking or skipping about, and thereby to leave a clearer, stronger impression in his mind.

Time honored rules of phraseology have established that, for emphasis, an item should stand first or last. This has been regarded as true whether one is speaking of the sentence, the paragraph, or the piece of writing as a whole. This is what is meant by order of emphasis. Whether the items placed first or last are remembered longest is open to some question, but certainly, the placing of anything, either at the beginning or at the end, gives it emphasis at the moment. Which of the two positions will give the greater emphasis depends upon the individual situation. Newspapers, for instance, feel that the lead paragraph is most important, because people want the news quickly and often do not read through to the end of the story. Orators need a strong beginning and a strong ending. The important thing is that the writer should remember that position is a device for gaining emphasis and should consciously use it.

Originating the Rough Draft

The first time a person is given the responsibility for originating a letter he is likely to feel somewhat panicky. This is not necessary as the letter will almost certainly be a routine letter which can be patterned after others in the file. If it is something out of the ordinary, it will probably be written by someone more experienced in letterwriting.

When given a writing job to do, the writer should find out the deadline or target date. The reason for this is so that he can budget his time effectively. Unless the letter is very brief and routine, a certain amount of time must be allotted for preparatory work, a certain amount for the rough draft, and a certain amount for polishing. The time apportioned for each should be according to the total amount of time available.

The file of related correspondence should be pulled to see how other letters were organized and worded. Thought must be given to all of the things which will be covered prior to writing the rough draft. The next thing is to write a rough draft. The writer should not worry too much at this point about spelling, punctuation, or other aspects of a finished style. The important thing is to get something in writing with concentration toward including all necessary information. Ideas should be expressed as clearly and in as effective order as possible. If the absolutely right word does not come immediately to mind, the writer should put down the best one he can think of, and mark the spot to improve later. If at all possible, the writer should get the rough draft written in some form or fashion because he can come back later and smooth it out.

If possible, the writer should allow a little time to elapse after finishing the rough draft before going over it again. If time permits, the rough draft should be put aside and something else worked on for awhile. When the writer returns to work on the draft he will normally be more objective and ways of improving it are usually more easily noted. Some things to look for are places where the continuity breaks down, where cutting can be done without losing the sense, and where words repeated too often have a jarring effect.

214223

206

As one becomes more experienced, he will develop his own individual work habits. As a beginner, the most important thing is to get his train of thought and his flow of language in motion, and keep going with a minimum of interruption.

When first beginning to re-read the letter, it should be gone through from start to finish, stopping only for the briefest of notes at places where the text could be improved. Trying to rewrite during this re-reading is not practical since it will often be found that the rewritten material does not fit with what comes next.

The rough draft should be read with a critical eye to determine that what has been written is correct, that it is clear, and that it is said as effectively as possible. The references should be reviewed in case there is any doubt as to the correctness of certain items or parts. Any matter of accuracy should not be left undetermined.

A writer should not be too upset if he cannot make sense out of some of his own sentences. This happens occasionally to even the best writers. He should be glad that these areas were found and can be corrected. If there is any doubt whether a passage will be clear to the reader, it should be read by someone who has not been thinking about the subject in the same light as the writer. Should this person have difficulty in understanding it, changes should be made even if it means taking out the writer's favorite sentence.

In the interest of effectiveness, the letter should be reviewed for useless words. Lazy and meaningless words should be cut out and the big ones cut down. The intensives (extremely, undoubtedly, very much) and the overworked introductory phrases (it is to be noted, it is a well known fact that, we call your attention to the fact that) should be taken out. The word "overworked" is used advisedly here, because the use of these phrases is not always unnecessary. Sometimes one of these phrases is needed; however, if it is not needed it should be deleted.

While reviewing the rough draft, the writer should look for overuse of certain words and replace them with substitutes. Likewise, all repetition of ideas should be culled out. Some repetition of both words and ideas is useful for emphasis, but a great deal is merely the result of carelessness. If something is not repeated deliberately and for a purpose, it should be changed.

The preferred style of the officer who will sign the letter should be kept in mind while reviewing the letter. Practically every officer who signs correspondence has a few favored words and phrases, and some which he will not allow. The writer should learn these as quickly as possible, thus eliminating a possible source of trouble or inconvenience.

Local policy must be followed regarding approval of rough drafts before smooth typing. In most activities the rule of commonsense is used—this is, if the letter is completely routine in every way, prior approval by the signer is not usually required; if policy is concerned, the draft must be approved.

A writer should not be upset if the rough draft he has written is revised by the reviewer. A rough draft is just that—it is used sometimes only as a point of departure for a complete rewrite. Improvement in letterwriting will be noted with practice; however, a writer may never get a letter out exactly as it was first written. It should be remembered that letters are normally signed by someone other than the drafter and the signer is naturally concerned that they are correct in every detail.

ACCEPTING CRITICISM.—Having reached this stage of correspondence preparation a writer will probably feel a certain pride in his accomplishment, which is only human nature. This is the danger point. A writer should not permit himself to become fond of the way he has expressed something. The minute this happens, he becomes reluctant to change his wording, and this means trouble in two ways. First, most writing can be improved, and therefore the door to criticism should not be closed, either personal criticism or that of another reader. Second, and this is basic to most military writing, the letter will be signed by someone else. If it has to go through several reviewers before it is signed, the writer might as well reconcile himself to the fact that it will be changed. Even if it goes directly to the person who will sign it, the writer should not feel distressed if the signer insists on having it worded his way prior to signing. After all, the signer takes the responsibility for the letter.

This does not mean that a writer should not defend what has been written if there is any misunderstanding, or that any of his reasoning has been overlooked. A certain amount of polite explanation is justifiable, and in fact, a part of a writer's duty. A writer should not feel that criticism is a personal attack on him. If he does,

his capacity to learn from experience and to improve will be diminished.

Checking Finished Correspondence

Correspondence usually must be checked by someone before it is presented for signature. This task commonly falls to the office supervisor in the smaller offices. Correspondence should be checked for the following:

1. Correct subject file classification number.
2. Inclusion of all required information or that the approved draft was followed exactly.
3. Correct titles of all addresses (action, via, and information).
4. Proper chain of command.
5. Enclosures properly labeled and attached in the required number of copies.
6. Proper number of copies.
7. Approved format for its type.

If typographical or spelling errors are found, they should be corrected in the locally approved manner. Ink corrections, if neatly made, are officially acceptable and recommended, but are not always acceptable to the officer signing the letter.

BUSINESS-FORM CORRESPONDENCE

The business-form letter is used for correspondence addressed to persons or agencies outside the Department of Defense who are not familiar with the naval form of correspondence. This includes individual civilians, most business firms, and many federal, state, and city officials. Just as each civilian firm has certain characteristic practices in the preparation of its letters, so the Navy, when it uses business style, follows certain rules.

Format

The format of an unclassified business-form letter prepared for transmission in a window envelope is illustrated in figure 3-1. Frequent reference to this figure will provide a better understanding of the discussion of business-form correspondence.

The first page of a business letter is typed on letterhead stationery. If printed stationery is not available, the letterhead is typed beginning 6 lines from the top of the page, centered on the page. Second and succeeding pages are prepared on plain paper comparable in quality with the letterhead.

A green tissue carbon copy of every outgoing letter should be made for the official files. Letterhead tissue, printed, typed, or stamped, should be used for all copies directed outside the originating office. Additional tissue copies, if required, are made in accordance with the local office practices.

The determining factor in setting the margins of a business-form letter to be transmitted in a regular envelope is its length. A letter less than one page long is centered to give it a well-balanced appearance. The left, right, and bottom margins of full page and multiple page letters are never less than 1 inch, and the top margin of second and succeeding pages is 1 inch.

The identification symbols and date are arranged the same in a business-form letter as they are in a naval letter.

If business-form correspondence is to receive special postal service, the words AIRMAIL, SPECIAL DELIVERY, REGISTERED, or CERTIFIED MAIL are typed in capitals or stamped at the left margin 2 lines above the address when an unclassified letter is to be mailed in a regular envelope, and 3 lines above the address if the letter is classified. On letters to be mailed in window envelopes, the postal designation is typed 4 lines below the last line of the address in the letterhead.

If a business-form letter is classified or designated "For Official Use Only," the appropriate security designation or security markings, including those required to downgrade a letter which is classified solely because it is forwarding a classified enclosure, are shown in the manner prescribed for the naval letter, with only the placement at the top of the page differing. The security classification or special markings are placed at the top of the first page on the line below the special postal service, if any, or 2 lines above the address.

The address begins at the left margin, the distance from the top depending on the length of the letter. If the letter is a full page or more, the address begins 2 lines below the special postal service or classification line, or 7 lines below the last line of the address in the letterhead if there is no special postal service or classification line. It is typed in block style without terminal punctuation. A 2-line address is double spaced. An address of 3 or more lines is single spaced. If it is desired to address the letter to the attention of an individual, the word "Attention," followed by the

14235

AZ.2

Figure 3-1.—Unclassified business-form letter format.

individual's name, is typed at the left margin 2 lines below the last line of the address.

When a letter is to be transmitted in a window envelope, the address begins 6 lines below the last line of the address in the letterhead and 2 lines below the special postal service, if any. Only the designation of special postal service, the address, and the attention line should appear in the window.

The salutation, followed by a colon, is typed at the left margin, 2 lines below the address or the attention notation, if the letter is to be

14226

mailed in a regular envelope. If the letter is to be transmitted in a window envelope, the salutation begins 5 lines below the address, or 3 lines below the attention notation. Generally, the salutation "Dear Mr." or "Gentlemen," is used.

The body or text of the letter begins 2 lines below the salutation. The text is single spaced, with 2 lines after each paragraph and subparagraph. Paragraphs of letters more than 8 lines long are typed in block style. The first lines of subparagraphs and subdivisions are indented 4 spaced successively, with the second and succeeding lines of each paragraph typed flush with the margin of the major paragraph. A letter of 8 lines or less may be double spaced, with the first line of each paragraph indented 4 spaces. Primary paragraphs are not numbered in a business-form letter.

The complimentary close is placed at the center of the page, 2 lines below the text of the letter. The complimentary close "Sincerely yours" is generally used.

The signature information, in block style, begins at the center of the page, 4 lines below the complimentary close. The signature lines consist of the name of the signing official, typed in capital letters; the military grade, if any; the functional title; and the authority line, if any.

When enclosures are to be transmitted with a letter, the abbreviated word "Encl.," followed by a colon, is placed at the left margin, 2 lines below the last line of the signature information. An enclosure list, each of which is numbered with an Arabic numeral in parentheses, followed by a brief description of the material, is typed immediately below the "Encl" notation. Enclosures which accompany the letter carry no special designation, but those which are to be sent under separate cover are identified by the designation "(SC)" in parentheses between the number and the description of the enclosure.

If the carbon copies of a letter are prepared for individuals or organizational units other than the addressee, the distribution appears only on the copies of the letter typed for internal use unless the writer specifically indicates that the distribution should be shown on all copies. When the distribution is shown on all copies, the words "Copy to," followed by a colon, are typed at the left margin 2 lines below the enclosure notation, or 2 lines below the last line of the signature information if there are no enclosures. The list of addressees for whom copies are prepared is typed immediately below the appropriate notation.

Paging, identification of second and succeeding pages, automatic time-phased downgrading and declassification marking, and assembly are as prescribed for a naval letter.

INSTRUCTIONS AND NOTICES

The Navy Directives System is designed to provide a uniform method of issuing written communications which prescribe or establish policy, organization, methods, or procedures, whether they require action or provide essential information. Standardization of subject classification through the use of numbers in definite series facilitates grouping the directives by subject, so that all related directives may be filed together regardless of the originating office. Standardization of the format allows use of binders available everywhere. The directives issued through this system are of two types—Instructions and Notices.

Instructions are those directives containing information of a continuing nature, or requiring action which cannot be completed in less than 6 months. An instruction has continuing reference value and is effective until the originator subsequently cancels or supersedes it.

Notices are directives of a one-time nature which contain information or require an action which is applicable for only a short time. The effective period of time covered by a Notice is limited to 6 months or less except when program requirements extend for a longer but definite period. In no case may a Notice be issued which is effective for more than a year. Each Notice must contain a specific, stated cancellation date for record purposes.

Directives prepared by AZ's are normally local in nature and do not apply to other activities. Local directives are very likely to duplicate others issued by higher authority, often needlessly. Since the Navy Directives System was established, Instructions have multiplied to the point that few personnel have the time to keep up with all those governing their official duties. In addition to this difficulty, local directives seldom are kept current due to the pressure of other work.

The issuance of unnecessary directives has been the subject of official concern on more than one occasion. Perhaps this is best expressed by the following quote from OpNav Notice 5216 of 11 September 1963 (Reduction

14237

of Administrative Correspondence in the Operating Forces), which was directed to all ships and stations:

"To the maximum practicable extent, avoid issuing repetitive Instructions. If the Navy Directives Manual is complied with, there can be no possible need for all of the duplication now existing. Directives should be complete enough so that no further repetitive issuance is necessary in the chain of command. There is evidence that many Instructions and Notices issued are not being complied with because there are too many for the individual units to keep corrected."

Before local directives are issued, the need for such Instructions and Notices should be established beyond doubt. A system to insure timely revision or cancellation must be installed and maintained conscientiously. An Instruction which is not required or one which is out of date is at best a nuisance, and at worst a serious obstacle.

Number Assignment

All directives issued in accordance with the Navy Directives System are classified by subject matter into one of 13 major numerical groups. Each group contains a thousand numbers, and is commonly referred to by the basic number of thousands; as, for instance, the 5000 series covers general administration and management and the 13000 series covers aeronautical and astronautical material.

The primary subjects are designated by the last three digits (the hundreds) of the numbers. Division into secondary and tertiary subject groups is made by the second and third numbers in the hundreds group, with the extent of division dependent upon the complexity of the subject.

The originator determines the basic number (everything in front of the decimal point) by consulting the detailed listing in SecNav Instruction P5210.11 (Series). Numbers after the decimal point are assigned consecutively for Instructions bearing the same subject classification number issued by the originator.

When there is a substantial change in an Instruction, it is rewritten, reissued, and carries the date of revision. Each revision is assigned the same subject classification number and consecutive number as the superseded Instruction, and is further identified by a suffix capital letter; the first revision A, the second B, etc.

When changes to Instructions are not extensive, they are issued as page replacements or pen changes or a combination of both. Additional pages are also issued as a change. These changes are issued in the form of change transmittals. A change transmittal describes the nature of the change. It is prepared in directive format and is identified by the same number as the instruction which it changes plus the assigned change number. For example, the first change transmittal applicable to OpNav Instruction 5442.2B would be identified as follows: OPNAVINST 5442.2B CH-1.

As in other correspondence, one zero added in front of a number indicates a classification of confidential, and two zeros are used for secret. A capital "P" in front of the subject number or in front of the classification designation indicates a book type, or pamphlet type Instruction.

Notices are issued with only subject classification numbers; that is, there is no decimal or number following the subject classification number. The date of issue serves to distinguish between Notices bearing the same number.

The complete code number P5210.11A on an Instruction can be broken down as shown in table 3-1.

Format

The format for Instructions and Notices is closely related to that of a naval letter. Figures 3-2 and 3-3 illustrate the format of a letter type directive.

The first page is prepared on the printed or a typed letterhead of the originating authority. Continuation pages are prepared on plain bond paper.

The minimum width of the top, bottom, right, and left margins is 1 inch.

The identification symbols are placed on the right side of the page 1 line below the last line of the letterhead. These symbols consist of the abbreviated title of the originating authority followed by "INST" or "NOTE" as appropriate, the subject classification number with applicable prefix-suffix elements, drafter's code or other identification, and the date of signature. These same identification symbols are placed at the top outside margin on continuation pages, except the drafter's code is omitted.

If a directive is classified, the appropriate designation is typed in capital letters 5 lines below the last line of the address in the

14238

Learning Experiences. Teaching methods and implied content for helping trainees achieve competencies identified for each unit or topic are stated. Each learning experience gives a specific method or methods to present the content, followed by a summary of evaluative techniques appropriate for the content. The learning experiences have been designed to cover the content needed to master the identified competencies.

Instructional Materials. Resources the instructor will need to collect or prepare in order to carry out the suggested learning experiences identified for each unit or topic are listed. Some of the devices are presented in more detail in the Appendix.

Instructor References. Selected books and pamphlets useful to the instructor in teaching the unit or topic are given.

The chart entitled, Time Allocation for Course Units, on page 26, gives the approximate number of hours needed for each unit and topic to prepare trainees to perform the required competencies for the different jobs. This will help the instructor to estimate the average length of training for each trainee. The time estimations are based on the kind of content to be covered in each unit and the degree of skill the trainee is expected to develop in relation to the actual job.

OSDI 1421

Table 3-1.—Breakdown of a complete code number.

letterhead, beginning at the left margin. In addition, on the first page the classification is marked or stamped at the top outside margin above the identification symbols and also typed in capital letters and marked or stamped at the bottom outside margin of the page. On continuation pages the classification is typed in capitals and marked or stamped at the top and bottom of the page.

The designation of the directive, consisting of the abbreviated title of the originating authority, type of directive (Instruction or Notice), and numerical designation including numerical classification begins at the left margin 2 lines below the classification, if any, or 5 lines below the last line of the address in the letterhead.

The title of the originating authority is shown on the "From" line. Action addressees are shown in the "To" line by individual titles, collective titles, or descriptive titles, depending on which is most appropriate. The words "Distribution List" may be used when the listing will be lengthy.

The "Subject," "Reference," and "Enclosure" lines are the same as in a naval letter.

In the text, paragraphs are normally numbered and lettered as in the naval letter format and paragraph titles are underlined.

Signature, distribution, and stocking information are entered as shown in figure 3-3.

Paragraphing

The arrangement of paragraphs within the directive is largely at the discretion of the originator and depends upon the subject. A few paragraphs are standardized and must be located in a specific sequence.

The purpose of each directive is stated in the first paragraph, including, when appropriate, the general applicability and nature of the action required.

Cancellation of another directive or document is contained in the second paragraph, except that when the sole purpose of a Notice is to cancel another directive, it may be included in the first paragraph.

If applicable, the last paragraph of each Instruction and next to last paragraph of each Notice indicates any reports required and any forms or records prescribed for use and states where the required forms may be obtained.

The last paragraph of each Notice states when or under what conditions the Notice is to be canceled. In all cases, a specific cancellation date (preferably the last day of the month) is provided for record purposes.

Descriptive paragraph titles, usually one or two words, are used for all major paragraphs and may be used for subparagraphs. The titles are written in capitals and lowercase, underlined and followed by a period, commencing two spaces after the number or letter designator on the paragraph or subparagraph. The text begins two spaces after the period on the same line.

Preparation

The first consideration in preparing a directive is that it must be complete. A subject important enough to be covered by a directive is important enough to warrant extra care in preparation. Before the reproducible master is typed, someone who has not worked on the directive should read it over in the rough. If something is not clear, it is relatively easy to correct at this time. there may be several who are indirectly concerned and who will need copies for information. The distribution should be determined carefully to avoid waste.

The action addressees and information addressees are listed separately at the end of the directive when a distribution list is used, so there is no confusion as to whether a given addressee is required to comply. This is particularly important if the directive requires reporting. Otherwise, confusion may cause certain reports to be delayed enough to destroy the validity of the data collected and prevent effective use of the information.

Cancellation

As stated before, Notices must be published with a specific cancellation date. Instructions are more permanent in nature, but may become obsolete over an extended period of time.

The originator should screen annually all Instructions issued by him. Those which have become obsolete and are no longer required may be canceled by a Notice. Those Instructions for which a need continues may be brought up to date with a change if most of the provisions remain valid. Extensive changes are usually made by rewriting and reissuing the Instruction.

REPORTS

One of the most important duties of the senior AZ assigned to a maintenance activity is that of preparing and supervising the preparation of reports.

A report is defined as any statistical or narrative information in written or tabular format requested by one activity from another for the purpose of forming policy, controlling operations, evaluating performance, or preparing publications or other reports.

Reports provide all levels of authority with information required for smooth and efficient operation. All data collected from reports is used for specific purposes; none is collected out of curiosity or incidental interest.

Reports are classified as (1) recurring reports, those required at specified intervals or on stated dates or upon the occurrence of an event or situation; (2) one-time reports, those required one time only and not intended to be recurring; (3) and feeder reports, those required for the sole purpose of preparing other reports.

Normally, a directive that specifies the submission of a report will furnish the required format to be used. If the report is made on a form, the directive states where the form can be procured and usually shows a sample report. It also shows submission times and activities to which the report is to be sent.

Personnel should exercise extreme caution when preparing reports. The data submitted should be accurate and the format followed in detail. Otherwise, the purpose of the report may be defeated. Erroneous data has little value when used for long range planning.

Reports should be forwarded with a covering letter only if the instructions for reporting require such letters, or if amplifying information must be furnished.

Specific reports with which AZ's are concerned are covered in other places in this training course.

Report Symbols

When a report is assigned a report symbol by the directive or other authority requiring the report, it indicates that it is included in the Reports Management Program. The report symbol will usually appear on the printed report form.

Certain types of reports are exempt from the control of the Reports Management Program, and are designated as "exempt" reports by the requiring authority. Examples of exempt reports are top secret and secret reports, and the majority of one-time reports.

MEMORANDUMS

The memorandum is a form of naval correspondence used for informal communications within and between headquarters components of the Navy Department, between fleet and force commanders and units of commands under their jurisdiction, and within a field activity. The memorandum is used by certain activities for formal communications, and it may be directed to one or more addressees.

For the most part, a memorandum is prepared in the same manner as a naval letter.

A memorandum may be typed on letterhead stationery, plain bond paper, or on U.S. Government Optional Form No. 10. When plain bond paper is used, the letterhead is stamped or typed in the center of the page, 6 lines from the top. Form 10 may be used instead of letterhead for

informal communications within the same command or office and may be typed or written by hand.

Carbon copies are not required of a memorandum dealing with a short-lived or inconsequential subject; however, if it is of significant importance to be a matter of record, a green tissue copy should be made.

Detailed instructions on the use and preparation of memorandums are contained in the Navy Correspondence Manual, SecNav Instruction 5216.5 (Series), which should be consulted in case of difficulty in memorandum preparation.

INCOMING CORRESPONDENCE

Official correspondence received by aircraft maintenance departments should ultimately become a part of the permanent records of the department. The routing required between the receipt of and the filing of the correspondence depends upon the type of information furnished and/or the action required.

The fact that official correspondence is originated implies that information is being requested or furnished. It follows that unless this information is properly disseminated, the mere originating has accomplished very little. Correspondence requesting a report does not produce the report unless the person responsible for its preparation receives the request.

The responsibility for the dissemination and proper handling of official correspondence is assigned to a specific organizational component of aircraft maintenance departments. A First Class or Chief AZ, in many instances, is assigned to this component, and in some cases may head such an organizational component.

Screening

Since most official correspondence is addressed to the commanding officer, it will be received by the administrative department. Correspondence concerning the aircraft maintenance department will be forwarded for appropriate action. Some of it may already have a routing sheet attached when received. The routing sheet attached by the administrative department may not indicate a complete routing for the aircraft maintenance department. Therefore, screening is required by the aircraft maintenance department to make sure it reaches the appropriate personnel.

The primary purpose for screening is to determine who should see the correspondence and in what sequence. Correspondence requiring immediate action should get in the hands of the personnel concerned as soon as possible. Screening of incoming correspondence should be done on at least a daily basis, preferably soon after the time mail is received in the department.

Routing

Immediately after screening has been completed, the correspondence should be routed so that appropriate action can be taken. Local procedures usually prescribe a standard routing for all incoming correspondence in addition to the routing to those individuals or organizational components primarily concerned with the individual communication.

A route sheet similar to the one shown in figure 3-4 is usually employed to insure the proper routing of correspondence. The intradepartmental section is utilized for internal routing within aircraft maintenance departments. The sheet should be prepared in duplicate, with the original attached to the correspondence being routed, and the copy being retained by the correspondence AZ. As the correspondence progresses through the routing indicated, appropriate action is taken and the routing sheet is initialed by the responsible individuals. When the routing is complete, the correspondence with the original route sheet is returned to the correspondence AZ for filing.

If the correspondence is in the nature of information, the routing may be placed on the correspondence itself. This may be accomplished by the use of a rubber stamp similar to that shown in figure 3-5. The date is the Julian date on which the correspondence started in routing.

Sometimes incoming correspondence is of such nature that more copies are needed than have been provided. It may then be necessary to make extra copies. In some cases, copies may be needed at the correspondence AZ's desk during the time the original is being routed. If copies are made for this purpose, they may be destroyed when the original is ready for filing.

Before routing correspondence to the person who is to take action on it, all previous related correspondence and other related documents should be taken from the files and attached. This preparation saves the time of the person who must take action. However, do not delay

delivery of mail while a search is being conducted for these papers.

Filing

Establishing and maintaining an adequate file system for correspondence is one of the easiest tasks the AZ will have, as well as one of the most important. Important correspondence improperly filed is of little value if it takes undue time to find it when needed. While the filing equipment available may not be the most modern and efficient, the senior AZ should have learned through past experience the best ways to utilize the available equipment. Normally, the office manager delegates most of the filing tasks to junior personnel in the office. As in anything else, the manager should be well aware of what is being done and should give such instructions as may be necessary to accomplish the job properly.

SELECTION OF FOLDERS.—One of the first things to be accomplished is selecting the folders which are to be used. Several slightly different kinds of file folders are available. Selection is normally based as much on personal preference as on any tangible evidence of superiority of one type over another. There are, however, a few points which should be considered.

Heavy board folders are relatively expensive. If the files are classed as records and are shipped to a records center, the folders are sent with the records and annual replacement may place a strain on funds. In addition, the added weight of the folders increases the cost of shipment.

Very lightweight folders will withstand normal handling without losing their stiffness. They are inexpensive and annual replacement of files sent to storage is practicable.

Folders with metal tabs or plastic capped tabs in which labels are inserted require more labor to prepare. In a small office, this may not be serious; however, in a large office, the extra time required would be significant. Subject classification numbers may be placed on the folders by any means that will produce neat labels which are easily read. Typed labels may cause eye strain and slow the job of filing if the light is poor, as it often is over files. Stencil pencils with fairly sharp points are easy and quick to use.

Folders are available with a variety of "cuts" indicating the number of different positions across the top for labels. The most common are one-third and one-fifth cuts. However, the most efficient file is one in which all labels are center positioned, so that the hand and eye travel in a straight line to find any folder. Again, this is not likely to be important if all your files are contained in one drawer, but would be a factor to consider in a larger operation.

FILES BY SUBJECT CLASSIFICATION.—The standardized system of filing correspondences is designed to speed the physical processes of filing and locating material for references. It is flexible enough to serve equally the smallest squadron aircraft maintenance office and the largest aircraft maintenance department ashore.

The system is based upon the same subject classification number series used for directives, and the detailed breakdown published in SecNav Instruction P5210.11 (Series) is used for both. For establishing a filing system, however, it is not necessary to have a folder for each subject code number. For example, the following numbers are found listed consecutively within series 13000-13999, "Aeronautical and Astronautical Material," under the primary subject group 13700-13799, "Engines and Engines Systems (Including Components and Accessories)":

13700 . . . .General
13710 . . . .Reciprocating
13720 . . . .Turboshaft and Jet
13730 . . . .Rocket

14245

13740 . . . .Nuclear
13760 . . . .Engine Fuel Systems
13770 . . . .Engine Electrical Systems
13780 . . . .Engine Cooling Systems
13790 . . . .Miscellaneous

If an activity has a heavy load of correspondence in the 13700-13799 area, it is conceivable that a folder for each of these subjects is needed. At the other extreme, a small activity may have few letters dealing with engines. The small activity would therefore ignore the secondary and tertiary breakdowns, indicated by the last two digits, and place all correspondence concerning engines in the folder marked 13700. A subject should be broken down and separated into smaller groups only when the amount of material filed would be bulky in one folder. If the total number of pieces of correspondence filed in the 13000-13999 series will fill only one folder, it is not necessary to make any further breakdowns.

If necessary, a particularly active file may be divided (or broken) into two or more folders, each clearly labeled with the inclusive dates of the material filed. A "general" subject file which needs such division should not be divided by date, but separated into more subjects.

Fastening filed correspondence in folders or on boards is so time consuming that it is now officially discouraged. (Special-purpose files in which the sequence must be preserved may be secured.) New material filed in a loose file should be placed at the back, with the top of the page to the left. Pieces of Correspondence removed from a file for reference purposes are more easily lost than a whole folder, and should be checked out of the file to an individual. A File Out Card (NAVEXOS 4178) should be used to show the location of removed material, with the card inserted in the file where the correspondence was removed. It is thus a simple matter to return the correspondence to the proper place in the sequence.

SEQUENTIAL FILES.—Special-purpose files of letters are sometimes kept in sequential order, such as a temporary accumulation on a board routed for general information. Messages are the only other correspondence normally filed in sequence by AZ's.

Message files must be established and maintained to meet the needs of the activity. An aircraft maintenance department in a squadron may need only two current files, one each for messages received and sent out during the current month. Larger installations may have files for periods as short as 1 day.

Regardless of the time interval used, the messages must be filed by date-time group. Frequent checks of the accuracy of filing are usually necessary, particularly when breaking in new personnel.

To preserve the sequence within the file, the messages are normally secured to a stiff paperboard back. Filing in inverse order (that is, with the latest dates on top) is the preferred method because of the time saved in filing.

MAINTENANCE AND DISPOSAL OF LOGS AND RECORDS

Congress has passed laws governing the disposition of logs and records and has fixed penalities for their unauthorized destruction. These laws apply, not only to those that are classified, but also to all official government records. Therefore, it is imperative that senior AZ's know the importance of maintaining accurate records and procedures for their disposal.

Though sometimes monotonous, all tasks connected with files, including their disposition when no longer needed, must be taken seriously. Since the supervisor is responsible for the work of juniors, he may be directly involved in the problem of disposition.

Decisions whether to save or not to save cannot be avoided by simply saving everything. Sooner or later, filing cabinets fill up and something has to be done. No matter how firmly a person believes that if it is disposed of today, someone will want it tomorrow, he cannot go on collecting forever. On the other hand, the "if in doubt, throw it out" line of thought, if allowed to operate unchecked, goes to the opposite extreme.

Activities subject to periodic deployments should be especially mindful of logs and records disposal. Unnecessary space, time, and money are used if these activities allow their files to become crowded with nonessential material.

One of the duties of the senior AZ is to be able to tell what should be held in the files for a period of time and what should, or must, be destroyed or transferred for preservation.

DEFINITION OF RECORDS

To begin with, it is quite possible that not everything in the files is an official record.

14246

Pamphlets, books, and spare copies of letters or directives are sometimes allowed to take up space for long periods because no one took the time to decide whether they had any value. The first step in properly disposing of an official record is to be able to recognize one.

The basic legislation covering records disposal (Records Disposal Act of 1943) defines government records essentially as follows: All documentary material, including books, papers, maps, and photographs, made or received by an agency of the U.S. Government in connection with the transaction of public business and appropriate for preservation.

Navy Regulations defines official correspondence as all recorded communications sent or received by a person in the Naval Establishment in the execution of the duties of his office. It further provides that no person shall destroy or remove from official custody any records without proper authority.

Nonrecord material, then, may be defined as any material which serves no documentary or record purpose. Most of the files kept by AZ's fall into this category. Virtually all letters, particularly the important ones, are duplicates of material filed in the administrative department. Also, the administrative department retains a copy of most maintenance department reports for filing, and the maintenance department retains a copy for reference.

It is not always easy to distinguish between records and nonrecord material and apply a standard rule for each item. Disposal of Navy and Marine Corps Records, SecNav Instruction P5212.5 (Series), contains a listing of record material usually found in aeronautical activities and gives retention period for each. Most directives pertaining to aircraft maintenance activities that specify the keeping of records will also state the retention period for these records. It would not be sensible to try to memorize all the different items in the listing, but it would be worthwhile to make a listing of those items kept in aircraft maintenance department files and the retention period.

RECORDS MAINTENANCE

The 3-M System has simplified, to a great extent, the keeping of many aircraft maintenance and associated records through the use of data processing machines. Although there are still certain records which must be maintained, the task of maintaining them is relatively easy.

Most records are maintained for the purpose of providing a history of what has been accomplished or events that have taken place. Maintenance records are used to prepare reports which furnish information to various levels of command. Many maintenance reports are prepared by data services through the use of machines; therefore, maintenance activities have little or no use for certain completed 3-M System source documents.

The production control work center is responsible for maintaining files of completed work records. Most of the 3-M System source documents are retained for only a short period of time; however, local policy may require daily and monthly reports to be maintained for a longer period of time.

Processed source documents with historical value are retained for 6 months. This includes the single copy maintenance action form, copies 1 and 3 of the multicopy maintenance action form, and the technical directive compliance form. Support action forms and configuration control forms are destroyed when local validation of daily reports has been completed.

In addition to source documents, registers should be retained for a minimum of 3 months. A review of completed registers may disclose useful information to be forwarded to a work center regarding associated or repeat discrepancies.

Organizational level activities should file completed forms by bureau/serial number of equipment. Intermediate level activities should file completed forms by individual work center and components.

Completed equipment statistical data cards and aviation maintenance support equipment data cards serve no practical purpose once local validation of daily and monthly reports has been completed.

RECORDS CENTERS

Material not designated as being of permanent value may be held by the activity or shipped to the appropriate Federal records center for temporary retention, depending upon the length of time it is to be held. The retention periods vary from 3 months to several years.

Federal records centers have been established by the General Services Administration at locations conveniently accessible to the various districts and ocean areas.

14247

Federal records centers store records in cardboard cartons on steel shelving in low-cost warehouse type space. The cost of storing records in these centers is a small fraction of the cost of maintaining them in office spaces. Therefore, activities should utilize these facilities for storing long-term naval records when their use is practical and economical.

Activities are authorized to transfer records to Federal records centers under the following conditions:

1. When the records are specifically designated in SecNav Instruction P5212.5 (Series) for periodic transfer. In these cases, the records should be transferred as scheduled; they should be transferred earlier only if local storage space is not available and reference requirements are such that transfer will not hinder the activity's operations.

2. The records are designated in SecNav Instruction P5212.5 (Series) for permanent or indefinite retention. If no specific periodic transfer is prescribed, these should be transferred as soon as they have served the activity's immediate reference needs and reference to them has become relatively infrequent.

3. The retention period of records of a disestablished activity has not expired and the records are not required either by the cognizant departmental command or office or by an activity assuming responsibility for functions of the disestablished activity.

4. Records have a retention period of more than 4 years.

5. Records are inactive and are not required for local operating purposes, provided it is determined that savings can be effected by the transfer; that is, transportation to the center and center storage costs will not outweigh local storage costs.

Activities should not transfer records to Federal records centers under the following conditions:

1. When inactive files are eligible for destruction within a year. Handling and transportation costs generally will not justify such a transfer. An exception may be made when the volume is large and the records are utilizing urgently needed file equipment and office space.

2. When the quantity is less than 1 cubic foot of records. Small accumulations should be retained until the retention period expires or until the quantity accumulated is sufficient to justify transfer.

3. When retention periods for the file, or for parts of the file, already have expired.

BREAKING FILES

To break the files means simply to close the entire file and start an identical file to run until the next break. The broken file, since it is relatively inactive, is put in a less convenient location.

In order that records may be disposed of systematically and in blocks, files must be broken periodically and a new file series begun. This makes the later job of separation and removing the records for destruction or transfer much easier. When to break the files is a local problem, but the usually accepted method is to do so at the end of each calendar year. If the volume of correspondence is too large for this, this may be done at the end of June as well. Since some records reach the age for destruction every day, it is perfectly legal to remove and destroy them day by day, though it is not very practical.

PACKING FOR SHIPMENT

Records are packed in their original file arrangement in standard cartons 15 by 10 by 12 inches in size. These cartons are supplied by the records center on request. Each carton holds 1 cubic foot of material. Letter-size documents are packed on the 12-inch side of the carton and legal-size documents on the 15-inch side. Odd-size items which are not suitable for shipment in the standard carton may be shipped in the most practical container available. Records are grouped by organizational unit and placed in containers in the original filing sequence.

In addition to the addressee, the name and address of the transferring activity and the sequential box number (i.e. 1 of 10) should be clearly marked on the narrow end of each container. Standard gummed lables are permissive, but crayon or stenciled labels are preferred. They are more readily visible and are easily prepared.

A Records Transmittal and Receipt Form (Standard Form 135) is used as a transfer document when transferring records to a Federal records center. This form should be prepared in triplicate for each records series to be shipped. One copy of the completed form should be placed in front of the first box of the records

14248

FASDI.

UNIT I - USE AND CARE OF FABRICS

Competencies

- Identify the characteristics of fabrics by label information, appearance, feel, and identification tests.
- Recognize the special features of fabrics which influence the sewing techniques and the equipment used.
- Give proper care to various types of fabrics.

Motivating Procedure

Have students examine a variety of fabrics with different fibers, fabric construction, and finishes. Give a quiz to help trainees pinpoint their scope of knowledge regarding fabrics.

Learning Experiences

- Discuss the information the law requires on labels and also the supplementary information that is often included by using the labels from the fabrics that were displayed.
- Make a chart entitled, Fibers - Characteristics and Care, on the chalkboard and/or distribute charts with the following headings: Generic Term, Trade Name, Fabric Type, Properties, and Care Procedure. Start the chart with four or five labels from ready-to-wear garments and complete by using other resources.
- Have trainees identify the fiber content of several fabrics by using a burning test. Ask trainees to tell how the fiber content affects construction techniques. Use a guide sheet and an information sheet as the basis for the test. See Appendix D and E.
- Arrange a field trip to a store selling fabrics. Have trainees identify fabrics by name and determine fiber content from hang tag or label on bolt of fabric. Discuss good buying habits with the fabric buyer.
- Have students make a collection of fabric samples. For each sample identify the fiber content and give the required care and special sewing instructions.
- Discuss the advantages and disadvantages of various fabric finishes such as permanent press, water resistance, spot resistance, wrinkle resistance, and lamination. Use samples or garments to show construction or alteration techniques needed for each specific fabric finish.

Instructional Materials

- Various types of fabrics

1423

being readied for shipment. The other two copies should be forwarded under separate cover to the Federal records center to which the records are being shipped. Upon receipt of the shipment, the center will return an acknowledged copy of the transmittal form to the transferring activity.

Activities may prepare the form in quadruplicate and keep the fourth copy as a suspense record of the shipment. When this is done, the suspense copy should be pulled and destroyed as soon as the acknowledged copy is received.

The Standard Form 135 should be properly completed so that it provides the center with adequate information for servicing and disposing of the records. Folder by folder listings or other elaborate descriptions as a rule should not be necessary. The information provided should include the retention period applicable to each record series on the transfer form and the date it will be eligible for destruction.

CLASSIFIED RECORDS

Before classified records are shipped, every effort should be made to declassify or downgrade them under the provisions of OpNav Instruction 5500.40 (Series). Those that cannot be declassified should be carefully inventoried and shipped in accordance with security regulations contained in the Navy Security Manual for Classified Information.

SERVICE ON RECORDS

The term "service" as used in connection with records centers refers to the reference service provided by the centers. Records stored in centers which are needed for references or information may be requested from the center.

Records centers are authorized to provide reference service only to, or with the permission of, the activity transferring the records. Request for information or documents received from other than the transferring activity are honored only with the approval of the transferring activity. If that activity is disestablished, the approval is obtained from the former activity's management command or office. Therefore, to eliminate needless correspondence and the need for repetitive approvals, transferring activities are encouraged to grant blanket approval to the center for the release of information or release of the files. When authorized to do so, the records center holding the records will compile or extract information from the records on request.

RECORDS DESTRUCTION

Most unclassified records are actually destroyed in the office. However, if large quantities are involved, they may be sold for wastepaper or scrapped. Classified items must be destroyed by burning in accordance with current security regulations.

At sea, unclassified records as well as those classified should be burned. Ashore, unclassified records may be scrapped or sold as wastepaper, provided the records are either treated to destroy word content (such as by shredding) or have inserted in the contract a clause prohibiting the resale of the records or their use as records or documents. Nitrocellulose base film, whether at sea or ashore, is usually destroyed by burning, since it can be a fire hazard.

When a state of war exists or when hostile action appears imminent, a commander may destroy records as an emergency measure. Reasons might be that retention of the records is prejudicial to the best interests of the country or that the space that the records take up is urgently needed for more important military purposes. In cases of this nature, the commander notifies the Navy Management Office that the records have been destroyed.

Federal law makes it mandatory that those records scheduled for destruction must be destroyed. This does not mean, however, that each item must be destroyed on the day authorized for destruction. Individual commands may establish the type of destruction program they deem necessary, based on when they break the file, such as quarterly, semiannually, or annually. What the law intends is that those records no longer having value should not take up valuable space over long periods of time. This is especially important on ships, where every square foot of space has at least one allotted purpose.

It might be emphasized that records are not to be destroyed before the scheduled destruction date, except in cases of emergency. They may be sent to a records center for retention until the destruction date.

AIRCRAFT LOGS DISPOSAL

Logs and records for aircraft stricken from the Navy inventory are disposed of as follows:

1. The logs and records of destroyed aircraft are disposed of locally after necessary investigation and preparation of required reports.

14249

2. The logs and records of aircraft sold or transferred to other than Navy custody accompany the aircraft unless otherwise directed by the controlling custodian. If the logs and records contain classified information, it must be removed or cleared for release through appropriate channels prior to transfer or sale.

3. The logs and records for experimental aircraft and those considered to be of historical value are forwarded to the Director, Federal Records Center, Alexandria, Virginia 22314.

4. The logs and records covering aircraft and/or equipment that have been involved in accidents resulting in death or injury to any person, or substantial damage to other than government property are retained by the operating activity for a period of 1 year. At the end of this period they are forwarded to the Federal Records Center in Alexandria.

14250

14250

Chapter 4

MAINTENANCE CONTROL

In order for any activity to meet its assigned responsibilities, a certain amount of control must be exercised. In aircraft maintenance activities, most of this control is accomplished by a properly functioning production control work center.

NOTE: The recent reorganization of Organizational and Intermediate maintenance activities not only relocated certain elements, but also made some name changes. One of these name changes is production control which, in the past, was called maintenance control. The terms production control, production control work center, maintenance control, and maintenance control work center are used synonymously in this training course.

The production control work center of aircraft maintenance departments is the starting point of practically all aircraft maintenance operations and is responsible for the production effort of the entire department. It is headed by the Maintenance/Material Control Officer who meets his responsibilities by coordination, monitoring, and direction of all activities of the production divisions, including expeditious processing of parts and materials.

The gathering, recording, and dissemination of all the various types of status information to efficiently employ the maintenance resources are prime responsibilities of production control. Further, the control of the entire workload and work effort of the maintenance department is a significant phase of the overall production control function.

A thorough working knowledge of production control administration should enable a leading AZ to perform his duties effectively. When assigned a task, he will know where to get needed information immediately, as well as the procedures to be followed for procuring parts and equipment. On a day-to-day basis, the knowledge he possesses will be reflected in the smoothness and ease with which he works and in the efficiency of his activity with regard to maintenance problems. Any AZ First Class or Chief competing for advancement in rating should understand that a sound knowledge of aviation maintenance administration is of utmost importance prior to his entering the competition.

The tasks performed in production control of Organizational and Intermediate level maintenance activities are somewhat related, and primary coverage, in this training manual, is devoted to the Organizational level.

ORGANIZATIONAL MAINTENANCE

The functions of production control include planning, scheduling, supervising, and providing positive control of all maintenance performed on assigned aircraft. The priority of work to be accomplished, utilization and adequacy of facilities, and availability of manpower, skills, tools, and support equipment are factors which should be considered when accomplishing these tasks.

All activities that have reporting custody of naval aircraft have the responsibility of maintaining all of the records, including logbooks, for these aircraft and their component parts, in an up-to-date status at all times. Senior AZ's assigned to production control are responsible for the compilation of various records and reports, assist in workload planning and scheduling for the department, and supervise the operation of the production control work center.

Some production control responsibilities are as follows:

1. Plan and schedule maintenance necessary to meet the scheduled mission commitments.
2. Insure all concerned are advised of maintenance capabilities, shortcomings, and adherence to the schedule.
3. Administer work control by authorizing and assigning jobs, work priorities, and completion times.

14251

4. Schedule aircraft through all phases of maintenance and release to operations.

5. Maintain status and location of each aircraft, critical categories of maintenance support equipment, and all maintenance in progress.

6. Coordinate the scheduling and loading of aircraft, to meet operational schedules, with the armament branch supervisor.

7. Review and determine parts requirements, with appropriate assistance, to complete jobs.

8. Assist in the development of improved maintenance techniques.

9. Coordinate with quality assurance in the scheduling of inspections.

10. Maintain completed source document files.

ORGANIZATION

This section is not intended to portray a standard organization for a production control work center; however, some possible arrangements are discussed.

Current instructions have directed the establishment of the production control work center within the framework of aircraft maintenance departments. As previously stated, the Maintenance/Material Control Officer is in charge of this element, and he is responsible for the production effort of the department.

The Production Control Chief, commonly referred to as the Maintenance Control Chief or Maintenance Chief, is the direct representative of the Maintenance/Material Control Officer. Under the authority delegated to him by the Maintenance/Material Control Officer, and with production division officers' concurrence, he directs, monitors, and supervises the day-to-day efforts of the production divisions. This direction is exercised through production division enlisted supervisors. He maintains liaison with enlisted supervisors of other departments and is responsible to the Maintenance/Material Control Officer for the overall production effort of the department.

In most cases, the production control chief is a Senior or Master Chief; however, due to rate and number of assigned personnel, size of activity, etc., this billet may be assigned to personnel in pay grade E-7. Some activities may have more than one chief assigned to this work center, in which case one would possibly be the production control chief and be primarily concerned with liaison between the production divisions and aircraft readiness, while another may be responsible for the administrative functions of the division. These administrative functions include supervision of logbooks, status boards, and maintenance of files as well as overall supervision of the office personnel.

The variety of tasks performed in production control makes it possible to divide the work center into sections or elements. These could include such as the following:

1. Planning.
2. Scheduling.
3. Records.
4. Reports.

The planning section is concerned with the overall maintenance plan of the department. The various maintenance tasks are scheduled and assigned for accomplishment by the scheduling section. The records section maintains the aircraft logs and related records. All required aircraft and engine accounting reports are prepared by the reports section. In some activities some of these sections may be combined, in which case planning and scheduling might be combined since their functions are related; likewise, the records and reports sections might be combined.

Production control should be located, equipped, and arranged to facilitate the gathering, posting, and recording of status information essential and significant to maintenance for successful support of operations. Production control is the nerve center of the entire maintenance function. It has to be the focal point where all information is assembled, arranged, and weighed to ascertain what actions are necessary to satisfactorily complete a particular standard or objective.

WORKLOAD PLANNING, SCHEDULING, AND ASSIGNMENT

Production control, through proper planning, scheduling, and assignment of the workload, provides all maintenance supervisory personnel with information on what management wants done and when completion is required. Efficient use of maintenance facilities is obtained by following carefully prepared maintenance plans and schedules coordinated with all activities directly or indirectly concerned. Careful planning, scheduling, and assignment insure efficient use of facilities and manpower and result in an uninterrupted flow of high quality maintenance.

Planning and scheduling does not end in production control. Each work center must do its

14252

14251

own internal scheduling. Each must consider manpower, supplies, facilities, tools, and the overall maintenance schedule. The capabilities of all maintenance activities are directed toward the objective represented by the maintenance schedule. The aircraft and all necessary personnel, tools, equipment, and supplies must be at the proper place at the proper time to allow production to proceed as scheduled.

The effective utilization of maintenance assets depends on the ability of production control to evaluate and use available information and to plan accordingly. Information must be obtained on operational objectives, quantity of aircraft involved, nature of support required, manpower availability, duration of the operation, and availability of material.

In the final analysis the main objective of the maintenance department is to provide operations with the maximum number of ready aircraft. The AZ assigned to production control will find it necessary to maintain close liaison with the operations department in order to meet the assigned operational commitments. He should be familiar with operational schedules as they play an important role in maintenance planning and scheduling.

A prerequisite to maintenance planning is a sound operational schedule insofar as practicable which provides required operational hours and allows sufficient downtime for the accomplishment of quality maintenance. Operational schedules for equipment should be compatible with maintenance capability and afford the best use of maintenance resources to prevent the loss of manhours which result from periods of idleness. When operational schedules are firm, production control personnel can translate the operational schedule into a maintenance plan designed to accomplish the requirement. The welfare of maintenance personnel (duty hours, overtime, etc.) should be considered when forming any work schedule.

One of the first requirements of scheduling is to find out what type and how much equipment is required for an operation, when, for how long, and for what purpose. This requirement is fulfilled by the operational schedule established in coordination with the operations officer. Any operational schedule must be thought of as a team concept where the operations and maintenance departments coordinate their schedules to accommodate the needs of both.

Operations must have enough equipment to fulfill their mission and training requirements, and maintenance must know when and how long the equipment is to be available for maintenance. Aircraft required for operational requirements should be ready as scheduled, and utilized as scheduled. Operational or maintenance delays in the use or provision of the required aircraft disrupts both the operational and maintenance schedules. Weapons loading, maintenance training, etc., should be planned into the schedule.

If possible the operational schedule should be established on a monthly basis and prepared so that the necessary operational hours are distributed as uniformly as possible throughout the month, to employ the maintenance department effectively. The schedule should be published in a form all personnel can easily understand and use. It is essential that wide dissemination be made to the lowest echelon of maintenance supervision and to the pertinent support activities such as supply, AMD, etc.

In order that maintenance can fulfill its obligations, the required number of aircraft and support equipment must be provided at the specified time. Scheduling and planning within maintenance is the only way in which this job can be properly accomplished. Therefore, to implement the maintenance schedule, a monthly maintenance plan should be prepared and published. This plan should include the date and hour, as far in advance as practicable, when scheduled events such as inspections will be performed. Thus, by scheduled control of predictable maintenance consistent with available maintenance resources, a reserve capability is maintained for unpredictable or unscheduled work.

Every effort should be made to prevent disruption of the schedule. Maintenance planning should include predictable maintenance factors such as manhours and material standards, flow times for maintenance, aircraft turnaround, and replacement schedules. Allowances, calculated from the maintenance data collection system, should be made for unpredictable maintenance such as engine failures, equipment failures, etc.

Full consideration must be given maintenance personnel, shop support equipment, electronics, photographic, communications, and weapons requirements so that the maintenance plan is complete and less susceptible to last minute changes. This plan should be reviewed and signed by competent authority and published as a maintenance order. During the month, production control should note variations from the monthly maintenance plan and initiate actions

14253

necessary to adjust the maintenance capabilities to meet the variations noted. The variations from the previous month's plan should also be noted and used as factors in refining the maintenance plans for the following month's operation.

It is important that the maintenance plan be distributed and made known to all maintenance personnel. Maintenance personnel must be made aware, through complete discussion and understanding, of the participation that will be required. Work center supervisors should plan toward leveling off the peaks and valleys to provide constant production. The plan should be completed and distributed to all work centers involved at least 5 days prior to the beginning of the month.

Although the format and detailed arrangement of the maintenance plan is a command prerogative, the plan should contain information such as the following:

1. Operational hours and total sorties, flights, or commitments.

2. Number of aircraft required to be operationally ready.

3. Workload requirements including aircraft scheduled for inspection or Depot level maintenance with scheduled date of input and output; shop direct support requirements; engine in shop inspection and maintenance requirements; and weapons, photo, etc., requirements and loading.

4. In addition to the overall maintenance planning, detailed support requirements must be planned. Procedures must be established to insure complete coordination between the station/ship. The method of accomplishing this support planning is normally determined by each command.

5. The schedule of preinspection meetings should be included in the maintenance plan.

Monthly operational schedules, manhour accounting and maintenance production reports, and Daily Schedule Maintenance Planning Records are sources of information that may be used to assist in the formulation of the monthly maintenance plan.

Weekly maintenance planning is accomplished to firm the monthly maintenance plan. Maintenance, operations, and other concerned representatives should convene weekly and review the past week's operation and maintenance accomplishments. From this meeting should come the next week's schedule. The weekly maintenance schedule should be distributed no later than Friday preceding the effective week. During this meeting, operations should present any change in requirements from the monthly schedule. Operational requirements should be evaluated against maintenance capability and the schedule adjusted to satisfy each.

In addition to weekly refinements to the overall maintenance plan, day by day detailed planning is necessary. This short range planning can be accomplished in a variety of ways. However, procedures must be established to insure complete coordination between supervisory personnel, production control, and the supporting activities.

The monthly operational schedule may be adjusted weekly to fulfill changes in commitments and allow for changes caused by unforeseen occurrences. Weekly changes should be resolved by operations and maintenance during the latter part of each week prior to the week affected by the change.

Availability of aircraft by bureau number or side number to fulfill the requirements of the operational schedule must be provided to operations by production control. Mission and pilot/crew assignments for these aircraft remain an operations department prerogative.

The operational schedule must take the maintenance capability into consideration. This can be accomplished best by consideration of the workload generation, aircraft turnaround or recovery time, manning effectiveness, adequacy of facilities, and capability estimates for each maintenance activity; knowledge of established maintenance plans and schedules; and pertinent information on aircraft and equipment to be maintained (operationally ready status, Not Operationally Ready Supply (NORS) rates, etc.)

Controlling the flow of equipment to and through maintenance is partially accomplished by insuring that it is available for maintenance as scheduled. Adherence to established schedules is essential for retaining maintenance capability. Adequate control of maintenance requires schedules be maintained in a manner to prevent peaks and valleys in the workload and personnel utilization.

Unscheduled Maintenance

Unscheduled maintenance tasks, due to their nature and occurrence, cannot be included in the monthly maintenance plan. However, this type of maintenance should be anticipated and time allotted for its accomplishment. Unscheduled maintenance includes the correction of discrepancies found and reported on daily, preflight,

14254

postflight, and pilot's aircraft inspections, as well as those reported on yellow sheets. In most operating activities, the accomplishment of unscheduled maintenance will consume a large portion of the expended maintenance manhours; therefore, it is important that ample time be allotted for completion of this type of maintenance.

It is imperative that the scheduling element of production control be made aware of all discrepancies concerning assigned aircraft and related equipment so appropriate corrective action may be taken. When scheduling and assigning this type of maintenance for completion, particular attention must be given to operational schedules. These schedules normally show the operational commitments of each aircraft; therefore, the urgency of need of the aircraft is a major factor to be considered when planning, scheduling, and assigning this type of maintenance for completion. Other factors to be considered are availability of manpower, type or extent of discrepancies, workload, and work priorities to be assigned.

Work priorities affect all elements of the maintenance activity and should be considered in all actions, especially unscheduled maintenance. Work priorities are essential to the proper and timely distribution of the maintenance effort and should be centrally controlled by production control. Supervisors at all levels must know which job is to be given emphasis; thus, work assignments can be controlled and production effort applied to desired projects. There are three work priorities used by maintenance activities—Priority One, Immediate Action; Priority Two, Urgent Action; and Priority Three, Routine Action.

Work priorities may vary daily or hourly, depending on the flight schedule and the unscheduled maintenance workload. It is important that realistic priorities be assigned to the various maintenance tasks and the system not be abused or the purpose of the system will probably be defeated.

Unscheduled maintenance planning, scheduling, and assignment are required on a day-to-day or even hour-to-hour basis. Normally, very little planning can be done prior to actual discrepancy discovery. By monitoring the flight schedule, production control keeps the various work center supervisors informed of aircraft launch and recovery times. This information makes it possible for the work center supervisors to plan their workload assignments in such a manner as to have maintenance personnel available to perform unscheduled maintenance, should it be required.

Reported discrepancies of such extent as to down the aircraft should naturally receive prime attention and be assigned for completion first; however, up gripes should receive proper attention. If nongrounding discrepancies are allowed to accumulate on a particular aircraft, they may develop into a state which could impair mission capability of the aircraft. Individually, these minor discrepancies may not be cause to down the aircraft, but when considered collectively, they may be of such extent as to prevent the aircraft from performing its assigned function and cause the aircraft to be downed. These discrepancies should be scheduled and assigned for completion as soon as the aircraft is available and the workload permits.

Scheduled Maintenance

Scheduled maintenance consists of those maintenance tasks which are known in advance and can be included in the monthly maintenance plan. This type of maintenance is associated with the Planned Maintenance System and pertains to preventive rather than corrective maintenance. The major portion of scheduled maintenance performed by operating activities consists of calendar periodic inspections and daily special inspections.

Inspections, varying in scope, purpose, and frequency, are required to be performed on naval aircraft to insure that assigned aircraft are retained in a serviceable condition. Under the calendar inspection system, the appropriate inspection is conducted on the expiration of a specified number of calendar weeks. Inspections and maintenance requirements promulgated in Periodic Maintenance Requirements Manuals are programed and referred to as odd and even calendar inspections.

The calendar inspection system is an efficient system from a maintenance management standpoint. When aircraft are inspected under this system, the workload planning operation is simplified and the scheduled maintenance in process is automatically stabilized.

The first inspection interval subsequent to Navy acceptance of a new aircraft commences on the date of the acceptance test flight. A first calendar odd inspection is performed at the completion of this first interval with subsequent inspections performed in the sequence prescribed by the applicable Periodic Maintenance Requirements Manual.

14255

The standard rework process includes the next calendar inspection due. The first inspection interval subsequent to standard rework commences on the date entered in the Aircraft Logbook by the rework activity certifying accomplishment of the equivalent calendar inspection. The next calendar inspection due is performed at the completion of this first interval and subsequent inspections are in the sequence prescribed by the applicable Periodic Maintenance Requirements Manual.

During special rework, the rework activity accomplishes the next inspection due if the out-of-service time combined with rework is such that one or more periodic inspections become due. The accomplishment of calendar inspections during in-service special rework must be negotiated with the controlling custodian or designated representative prior to induction. Periodic inspections subsequent to special rework therefore continue in the same sequence as they did prior to special rework. All periodic inspections accomplished by rework activities are noted in the Aircraft Logbook and Aeronautical Equipment Service Records.

Aircraft are inspected on the calendar interval established by NavAir Instructions or on an adjusted interval as specified by the controlling custodian. Calendar periodic inspections are programed in multiples of calendar weeks, computed from induction date to induction date, irrespective of days consumed performing the individual inspection. Therefore, an aircraft assigned a 13-week interval would be inducted into the next calendar inspection 13 weeks after the original induction date.

The calendar inspection system is placed into operation by dividing the number of aircraft assigned into the calendar inspection interval (for example, 13, 17, or 22 weeks) and programing scheduled maintenance and inspection requirements accordingly. Figure 4-1 graphically depicts the calendar inspection schedule of a typical 12-aircraft squadron operating an aircraft model that is assigned a 13-week inspection interval. One aircraft could be inducted into check every week for 12 successive weeks and then leave 1 week with no induction. The inspection cycle would start over again following the week with no induction.

To meet unusual situations and facilitate workload scheduling, a period of plus or minus 1 week, or portion thereof, may be applied to the authorized calendar inspection interval. However, in each instance each deviation applies only to the immediate inspection due. Successive deviations, if required, are computed from the date on which the inspection would have been due if the preceding deviation had not been granted.

To eliminate peaks and valleys in the workload, the overall pattern formed by the correct programing of all aircraft should be one of alternating odd calendars and even calendars.

AZ.7

Figure 4-1.—Typical inspection cycle.

14256

Once the schedule is established, it should be maintained, except for those vacancies resulting from transfer, strikes, or standard rework. Replacement and/or return aircraft should be positioned in schedule vacancies and schedule integrity maintained.

Induction of new and reworked aircraft into an established calendar inspection schedule may require repeating or performing an otherwise unnecessary inspection to insure that the scheduled workload pattern remains one of alternating odd and even calendar inspections. (See fig. 4-2 for some examples of induction into the inspection cycle.) Newly received aircraft are required to be firmly established in the calendar inspection schedule within a period not to exceed one inspection interval.

Operating activities are authorized to increase the depth of any inspection but cannot decrease it. Whenever the depth of any inspection is increased to meet unusual or special circumstances, the inspection is recorded only as the type which was due in accordance with the programed sequence. Conditional inspections to an appropriate depth may be ordered whenever excessive utilization during the operating interval is considered to have impaired the material reliability or integrity of the aircraft. Such inspections are in addition to programed requirements and in no way affect the requirement for the accomplishment of the next regularly scheduled inspection. Logbook entries are required for conditional inspections.

Oftentimes an activity adds locally established inspection requirements to existing Maintenance Requirements Cards. The need for these requirements may be due to climatic or other environmental operating conditions. A copy of all locally established inspection requirements must be submitted to the Naval Air Technical Services Facility on an Unsatisfactory Material/Condition Report. The material conditions or technical directive generating the inspection requirements must also be noted.

Specific model aircraft inspection requirements as established and published by direction of the Commander, Naval Air Systems Command are minimum requirements and, as such, are mandatory. Temporary waiver of individual inspections may be made by the reporting custodian or higher operational authority in

AZ.8

Figure 4-2.—Examples of induction date scheduling.

14257

order to meet priority operational commitments or combat necessity. Temporary waiver authority should not cause major schedule disruption; however, should this occur, the normal pattern of inspection schedules should be reestablished as soon as possible.

Although the monthly maintenance plan (previously discussed) portrays the overall scheduled maintenance plan of the particular activity, other planning and scheduling actions are required. Some of these are discussed in the following paragraphs.

The Daily Schedule Maintenance Planning Record, NavAir Form 4730/1, has been provided for use by maintenance activities to plan and project the daily scheduled maintenance requirements for each individual aircraft between calendar periodic maintenance periods. This form is filled out to cover the complete calendar period. It should be completed while the aircraft is undergoing calendar periodic maintenance so that all scheduled maintenance for the subsequent operating period is known at the time the aircraft is returned to an operating status. It aids in assuring that all known maintenance requirements are scheduled on time as well as aids in workload planning.

The form provides a number of spaces for each day in which to enter Maintenance Requirements Card numbers that require compliance on a basis other than every day and provides a means for writing in all other scheduled maintenance due during the calendar maintenance period designated for the aircraft.

Special inspections (7-day, 10-day, 20-day, etc.) specified in the Periodic Maintenance Requirements Manual are performed concurrently with scheduled calendar inspections when the time authorized for the special inspection is not exceeded. When the time interval will be exceeded during the calendar period inspection interval, the special inspection is scheduled and accomplished as part of the daily inspection falling nearest to the requirement. Maintenance Requirements Card numbers for these special inspections are listed for compliance on the Daily Schedule Maintenance Planning Record under the date they will come due. Proper use of this form will assist in the preparation of the monthly maintenance plan.

The Preflight / Postflight / Daily / In-flight Maintenance Record, NavAir Form 4730/2, is used in conjunction with the Daily Schedule Maintenance Planning Record to enable scheduled work to be assigned in a preplanned manner between calendar inspections. This form controls and assigns responsibility for preflight, postflight, in-flight, and daily scheduled maintenance, including the special and conditional work that may be required. These forms may be prepared daily or made up in numbers sufficient to cover a desired period of time.

Another planning action is the precalendar planning conference. Under the direction of the activity maintenance officer, the Maintenance/Material Control Officer holds a planning conference several days in advance of the calendar inspection due date with the calendar maintenance supervisor and representatives from quality assurance, material control, and the calendar inspection team.

The purpose of this conference is to prepare the Sequence Control Chart by adding on any existing additional requirements, procure personnel as required by the scheduled and add-on requirements, and pre-position material required. Representative items added on at this time are recent local or command maintenance items, discrepancies, component replacements, directive incorporations, and other like items which either cannot be anticipated or cannot be programed into all calendar inspections on a fixed basis. This procedure informs all concerned of exactly what management wants done on each individual calendar inspection so the workload can be adjusted as required to meet established schedules.

The Sequence Control Chart is the basic schedule of the calendar maintenance inspection. The Sequence Control Chart also serves as a work progress chart after the inspection begins. The Sequence Control Chart may require changes for optimum benefit and realistic usage during the inspection to schedule local maintenance items, component replacement, engine changes, and incorporation of technical directives.

TECHNICAL DIRECTIVE INCORPORATION.—Incorporation of changes and modifications to aircraft and related equipment must be expedited in order that all possible operational and safety advantages can be derived from the remaining life of the model concerned. Modification must be coordinated to achieve early availability of aircraft with optimum

standardized change configuration and minimum disruption of the normal operating cycle.

Letter type technical directives issued by or at the direction of the Commander, Naval Air Systems Command are the official medium for accomplishing aircraft and related equipment changes and modifications. The authorization to prepare a letter type technical directive is normally issued by the Commander, NavAirSysCom or the cognizant NavAirSysComRep. They are prepared by both Navy industrial and commercial activities.

Interim letter type technical directives are initially distributed by the originator to such activities as NavAirSysCom, NavAirSysComReps, CNO, ComNavAirLant, ComNavAirPac, etc. Further distribution of interim directives to operating activities both ashore and afloat is the responsibility of NavAirSysCom, CNO, and the major operating commands.

Formal printed letter type technical directives are distributed by the Naval Air Technical Services Facility. Advance distribution is normally made, as soon as possible, to such activities as NavAirSysCom, NavAirSysComReps, the major operating commands, etc. The Naval Air Technical Services Facility automatically distributes copies to activities and commands concerned in accordance with the requirements reflected in the latest NavWeps Form 5605/2 (Automatic Publications Request) submitted by the various activities. It is emphasized that effective operations of the automatic aeronautical publications distribution system is dependent upon the timely and accurate notification of requirements by means of NavWeps Form 5605/2.

NavAirSysCom instructions contain information relative to the preparation, issue, and incorporation of changes and modifications to aircraft and related equipment. These instructions also establish procedures for recording and listing, by specific aircraft bureau number, the applicability and incorporation of all letter type technical directives which specify a logbook entry. In addition to these instructions, air type commanders have issued instructions concerning the incorporation of changes in their area of control.

On receipt of the advance copy of a change, air type commanders assign to each a code which delineates incorporation tasks. Major consideration in assigning these codes are the magnitude of the work involved and the effect of the changes on flight safety and operational readiness. Code assignments are distributed by the respective NavAirSysComRep on the Aeronautical Technical Directives Not-Incorporated List No. 2. This listing also furnishes information on the kits required to accomplish the change. These codes denote whether the change is to be incorporated by the reporting custodian, by field modification teams, or by rework activities during aircraft rework.

Aircraft maintenance activities receive various directives concerning changes and modifications to assigned aircraft and equipment. A large portion of these directives are of such a nature that they can be scheduled for compliance along with aircraft calendar inspections. Other directives received are of an immediate nature and require incorporation in affected aircraft or equipment prior to further use. Directives of this type should be scheduled and assigned for immediate compliance and normally receive precedence over other nonurgent maintenance.

Changes or modifications may also be scheduled for completion when the particular aircraft concerned will be available due to other maintenance. In this case, particular attention must be given to the areas of the aircraft in which work is required. For example, most Avionics Changes require the removal of the equipment concerned in order to comply with the change/modification.

If the aircraft concerned is down for an engine change, fuel cell replacements, etc., electronics personnel could remove required equipment and incorporate necessary changes/modifications without interfering with other maintenance. Each directive contains a time limit for compliance, therefore, this is another important factor to be considered when scheduling and assigning directives for incorporation. Other factors to be considered are availability of kits/material, aircraft or equipment, and manpower; the workload, and estimated time required to accomplish the change/modification.

Periodically, preferably 3 weeks prior to the precalendar inspection conference, the logbooks, active SAMI file, and applicable configuration lists should be screened by the log yeoman or logbook supervisor. The purpose of this screening is to determine the need for any kits/materials and to insure that all directives not complied with are known at the time of the precalendar inspection conference so appropriate action may be taken to have them scheduled for compliance.

14259

14260

Production control must initiate action through the material control work center to procure any kits or material required to incorporate a change. This is usually done soon after the receipt of any approved, applicable technical directive requiring kits or material; however, if this system is not followed, screening is required to determine the need for kits or material. If, during screening, it is learned that required kits or materials to accomplish a particular change or modification have not been ordered, immediate action should be initiated for procurement of required materials.

Each technical directive lists the necessary change kits and material required for its compliance as well as a source. After the required materials are on hand, the technical directive should be scheduled and assigned for compliance, keeping in mind the factors mentioned.

The Technical Directives Compliance Form (TDCF) is used by maintenance activities to inform the material control work center of the need for kits or materials and also to record the accomplishment of technical directives. A brief discussion of this form is contained in the following paragraphs. A detailed discussion of this form is contained in AZ 3 & 2, NavPers 10391-A.

The TDCF, illustrated in figure 4-3, is a single page form that is used to document all technical directive maintenance actions. It is also used for preplanning workload and material requirements, assigning a technical directive for completion, and configuration accounting. Data obtained from these forms allows identification of all direct manhours expended complying with technical directives.

The TDCF is prepared and issued by production control. It is normally initiated upon receipt of each approved applicable technical directive or when compliance with a technical directive is assigned for incorporation. Much of the information required for completion of the form is known at this time. Referring to figure 4-3, the typed information is entered by production control and is available at the time of initiation of the form. The handscribed information is entered, as received or as actions take place, by the appropriate work center.

There are several factors which must be considered in determining the number of copies required. Under all conditions, an original and one copy are required. The original is forwarded to the primary work center when the maintenance action specified by the technical directive is assigned for completion. A suspense copy is held by production control until the work has been completed and the original has been received from the primary work center. The suspense copy is then discarded.

If kits or materials are required for completion, one copy is forwarded to the material control work center. This copy serves as the notification for material control to order required material. Upon ordering the material, the material control work center furnishes production control with the date ordered and stub number. This is entered on the original and suspense copy by production control. In a like manner, material control informs production control when the material is received. This date is also entered on both the original and suspense copy.

If more than one work center is involved in completion of the maintenance action, each assisting work center is provided a copy. This copy is used to document the manhours expended by that particular work center.

The TDCF is divided into five sections, and these sections are subdivided into numbered and lettered blocks. The information entered in these blocks consists of many of the same codes used in the completion of other source documents.

For the most part, the entries made on the TDCF by production control are self explanatory. Entries are made in the statistical data section by both production control and the production work center. Only the data from this section is keypunched by data services. The blocks of this section that are completed by production control are 1 through 6, 8, 12, 13, and, when required, 14.

All of the blocks in the maintenance control section are completed by production control. The information to be entered in blocks E through H of this section is normally listed in the technical directive.

The stock number of any material or kits required to accomplish the technical directive is entered in block A of the material control section by production control. Required material or kit stock numbers are usually listed in the technical directive.

The only entry required by production control in the work center section is block B. If applicable, the SAMI or CAMI number which refers to the technical directive being accomplished is entered in this block.

14280

action required, and replacement schedule of the components which must be replaced. Replacement items are indicated in operating hours, calendar time, or progressive aircraft rework periods, as appropriate.

All replacements designated in a specified number of hours have been based on flight hours with necessary adjustments to compensate for ground operating time. Those items designated for replacement at progressive aircraft rework are not intended for replacement by operating activities except for reasons of malfunction or failure.

The appropriate sections of the logbook should be screened for high time components at the same time screening is done to determine the need for change kits and directive incorporation. If this is accomplished prior to the precalendar inspection conference, personnel concerned can be informed of any components requiring replacement and they can plan accordingly. Once the aircraft enters inspection, replacements for components requiring change are ordered. After the required replacements are available, component replacements are scheduled for change along with other scheduled maintenance.

AIRCRAFT ACCEPTANCE AND TRANSFER

New aircraft are ordinarily accepted into the Navy inventory by the Naval Air Systems Command Representative located at the contractor's plant. Acceptance takes place when legal title to the aircraft leaves the contractor and is assumed by the Navy. The acceptance may be provisional; that is, the producer has some contractual responsibility yet to fulfill before the aircraft can be considered ready for issue. Until this responsibility is fulfilled, the aircraft is in a provisional acceptance status. After this original acceptance, aircraft are usually assigned to operating activities for service.

Once in the Navy inventory, a change in the reporting custody of an aircraft from one reporting custodian to another reporting custodian constitutes a receipt by the unit gaining reporting custody and a transfer by the unit losing reporting custody. The receipt and transfer occur simultaneously upon acceptance by the receiving unit.

If the reporting custodians involved are under different controlling custodians, a change in controlling custody also occurs, one gaining the aircraft simultaneously with loss by the other. Receipt of an aircraft by a reporting custodian without a corresponding transfer by another reporting custodian occurs only when an aircraft is added to the Navy inventory. Every Navy aircraft is at all times, from acceptance to separation, in the custody of one reporting and one controlling custodian. An aircraft remains in the reporting custody of the transferring unit until accepted by the receiving unit.

Operating activities receive and transfer aircraft frequently; therefore, senior AZ's should know some of the action involved. The following paragraphs cover some of the procedures for receiving and transferring naval aircraft.

Receiving Procedures

Aircraft are assigned and transferred from NavAirSysCom custody to the major operating commands on a NavAirSysCom Priority. A letter or message type directive is normally used to effect the transfer of aircraft from the major operating commands to operating squadrons. This transfer directive is known as an Aircraft Transfer Order (ATO). A copy of the ATO is normally received by all activities involved with the transfer and receipt of the aircraft concerned.

If the aircraft is delivered by a ferry pilot, a pilot not attached to either the transferring or receiving activity, every effort should be made to accept the aircraft as soon as possible so the ferry pilot will not be detained. Aircraft ferried by the Fleet Aircraft Ferry Squadrons for other commands are not in the reporting custody of the ferry squadron. The ferry pilot is the agent of the reporting custodian for whom he is ferrying the aircraft; therefore, discrepancies noted upon receipt of the aircraft should be resolved with the transferring activity and not the ferry pilot.

After acceptance of the aircraft, current directives require the accomplishment of an acceptance inspection. This inspection consists of an inventory of installed material and loose gear, configuration verification, functional test of appropriate emergency systems, and a thorough daily inspection. Accepting activities may elect to increase the depth of inspection if the aircraft condition indicates such action is necessary.

The inventory log/record serves as the instrument of transfer and signing of this log/record by the receiving activity denotes acceptance of the aircraft. It is important that

14262

the date the inventory log/record is signed be used on all records and reports concerning the acceptance of the aircraft.

The logs and records received with an aircraft should be carefully reviewed for completeness and accuracy as part of the acceptance procedure. Although all sections of the Aircraft Logbook are important, particular attention should be directed to the flight, inspection, and technical directives sections.

The flight section provides information relative to the past utilization of the aircraft. This section provides receiving activities required information concerning tour/period number, months accumulated in tour/period, flying hours accumulated in tour/period, and total flying hours since acceptance of the aircraft. This information is needed for proper submission of the OpNav XRAY message.

The inspection section must be consulted when phasing the aircraft into the receiving activity's inspection cycle. In determining the depth of acceptance inspections, consideration must be given to the termination date of the previously programed inspection interval. If induction into the receiving activity's inspection cycle is programed to occur prior to termination of the previously programed inspection interval, no special consideration is necessary. However, in the event induction into the receiving activity's inspection cycle is programed to occur subsequent to termination of the previously programed inspection interval, the acceptance inspection must include the calendar inspection that would have been due at the termination of the previously programed inspection interval.

The technical directives section should be reviewed together with the applicable configuration lists. The active and inactive SAMI files may be used to assist in determining if certain technical directives have been complied with on newly received aircraft. The bureau numbers of newly received aircraft should be added to all active SAMI's for compliance.

Aircraft and equipment logs and records provide a history of maintenance, operation, configuration, and in many cases, a control of maintenance schedules for time replacement of components and accessories. It is of utmost importance that reporting custodians maintain the logbooks and associated records for all assigned aircraft and equipment in an up-to-date status. There have been many instances of incomplete or poor logs and records maintenance that have necessitated unnecessary inspections and even overhaul of aeronautical components.

Activities receiving questionable or incomplete logs and records should request immediate corrective action by the delinquent activity. Obvious mistakes in recordkeeping may be corrected by the current custodian and initialed or signed off, as applicable, without reference to the previous custodian. Discrepancies requiring corrective action by the previous custodian may be signed off by the current custodian after receipt of correspondence conducting corrective action. In extreme cases, a receiving activity is fully justified in refusing to accept custody of aircraft or equipment with doubtful or incomplete logs and records.

The receiving activity should prepare an Aircraft Record "A" Card for its own records and submit an Aircraft Custody/Status Change Report (OpNav XRAY), denoting acceptance of the aircraft, to proper authority not later than 1200 hours of the day following acceptance. Appropriate engine record cards should be prepared and engine reports should also be submitted to proper authority.

In order to maintain local data services inventory control, an Equipment Statistical Data (ESD) Card should be submitted upon gain of an aircraft. The receiving activity should begin reporting as of 0001 hours of the date following the date of receipt. No provisions are made for splitting a day between two units, therefore, the transferring activity reports the aircraft up until 2400 hours of the date of transfer. The submission of the ESD card does not relieve an activity of the responsibility for the timely submission of an OpNav XRAY message. The ESD card reflecting receipt of an aircraft into an activity's custody is handscribed.

NOTE: It is important that the data entered on this card be correct in every respect. The data services unit uses the data entered in blocks 1, 2, 3, and 4 to prepare a supply of prepunched/preprinted cards to be used by the receiving activity in reporting other actions.

Completed ESD cards reporting gains should be forwarded to the analysis division not later than 0900 hours on the first working day following the transaction. The need for timely submission of inventory change data requires strict adherence to this time frame. These cards are processed by data services and the data extracted is used in various phases of aircraft accounting.

14263

Transferring Procedures

Aircraft transfer is another important task performed by operating activities. Although all divisions of the maintenance department are involved in aircraft transfer, senior AZ's assigned to production control coordinate the efforts of the production divisions and must be familiar with aircraft transfer actions.

There are several different types or categories of aircraft transfers. These include aircraft transferred from one controlling custodian to another controlling custodian for service, intrafleet transfers which apply to aircraft transferred from one reporting custodian to another within the same controlling custodian, and aircraft transferred to NavAirSysCom Fleet Support (NavAirSysCom FS) activities for repair, rework, or storage. The intrafleet transfer is the most common type and is normally directed by the controlling custodian.

The transferring activity should make the aircraft ready for transfer within 7 to 10 working days after receipt of a transfer directive, unless a specific transfer date or deadline is designated in the transfer directive. In instances where the time limit for transfer cannot be met, the transferring activity should notify the receiving activity and the originator of the transfer directive. The reason for delay should be cited and an estimated ready date furnished.

As in the case of aircraft acceptance, current instructions require the performance of a transfer inspection prior to transfer of an aircraft. While this does not necessarily include the performance of a calendar inspection, it should be of sufficient depth to insure that the aircraft is safe for flight. Performance of an odd or even calendar inspection as part of the transfer inspection is not normally required unless the next calendar inspection would become due during the flight to the receiving activity. Performance of special calendar inspections as part of the transfer inspection results, in many cases, in duplication of effort, erroneous logging of inspections, and decreased availability with little or no increase in flight safety. However, the transferring activity should perform such work and examination as required to insure the following:

1. Airworthiness.
2. Good material condition.
3. Proper configuration.
4. Completeness of inventory.
5. That the aircraft can carry out its assigned mission.

If transfer of an aircraft requires a ferry flight for delivery, there are additional requirements to be considered when performing the transfer inspection. NavAir Instruction 3700.3 (Series) sets forth the minimum operating requirements considered necessary for aircraft to be ferried. The enclosures to this instruction are checkoff lists which contain conditions to be met, prior to transfer, of reciprocating, jet, and rotary wing aircraft. Compliance with the provisions of this instructions requires a log entry to be made in the inspection section of the Aircraft Logbook.

Current instructions require the removal of low-time engines from aircraft destined for storage or overhaul. These low-time engines are replaced with engines nearing completion of their service life so as to fully utilize available operating engine hours. Applicable instructions concerning removal of low-time engines should be reviewed prior to completion of the transfer inspection in all cases of aircraft being transferred to storage.

All airframe changes for which approved engineering data and material are available and which are within the maintenance capability of the transferring activity should be incorporated prior to transfer of affected aircraft from one custodian to another unless otherwise agreed to by the receiving custodian. In case agreement cannot be reached, the question should be referred to the immediate common senior responsible for material assistance for resolution.

After completion of the transfer inspection and any additional maintenance tasks, engine changes, airframes changes, etc., the aircraft should have a test flight of sufficient duration to adequately perform the prescribed tests and determine which items, if any, require additional maintenance work.

All ammunition and pyrotechnics should be removed from the aircraft, excepting escape and survival systems. The aircraft must be inventoried and the inventory log/record completed in accordance with current NavAirSysCom instructions. If loose equipment and inventory items are forwarded by separate shipment to a receiving activity, the items shipped must be indicated on the inventory record. The method of shipment, bill of lading, and invoice numbers should be noted on the record or forwarded to the receiving activity by appropriate means as soon as known.

14264

The aircraft should be cleaned, corrosion removed and arrested, and the proper type of preservation, as specified in current preservation manuals or other appropriate directives, applied. All unit identification markings should also be removed. The aircraft should be transferred complete with all parts, accessories, and equipment. Any change kits on hand that cannot be incorporated should not be transferred as loose equipment, but should be turned back into the supply system.

The Aircraft Logbook should be reviewed to ascertain that it is complete and up to date. The monthly flight summary and equipment operating log(s) should be closed out in accordance with applicable instructions. Test flights performed in conjunction with the transfer should be logged prior to this closeout. All Custody and Transfer Record pages, NavAir Form 13090/21C, should be properly completed. The aircraft transfer order number, message, or other authority directing the transfer should be entered under authority for transfer on the Custody and Transfer Record. Ten most recent "B" parts of yellow sheets plus those that have not been completed should be transferred with the aircraft. In addition, completed Maintenance Action Forms, Technical Directive Compliance Forms, and records of all check flights for the preceding 6 months should be transferred with the aircraft.

When the aircraft is ready for delivery, all concerned should be notified in accordance with OpNav Instructions 3710.6 (Series), which contains instructions concerning ferry movement of aircraft.

After transfer of an aircraft, the transferring activity must submit an ESD card to data services reporting the loss. A prepunched/preprinted card is normally used for this purpose. All loss actions are effective as of 2400 hours on the date of transfer.

One of the final actions required in aircraft transfer is the completion of Transferred To section on the Aircraft Record "A" Card. Once completed, the card should be removed from the active file and retained in an inactive "A" card file for 6 months.

PREPARATION AND REVIEW OF RECORDS AND REPORTS

The senior AZ assigned to production control will be continuously concerned with records and reports. In order to properly manage naval aviation, various commands, offices, and activities must be kept current on what is happening to aircraft and related equipment being used. To furnish this information, operating squadrons must maintain various records from which the required reports are made. It is imperative that all reports submitted to higher authority are correct; therefore, accuracy in records maintenance and reports preparation cannot be overemphasized.

For the most part, reports are prepared and submitted in compliance with a message or instruction. They contain consolidated information or facts of the record of something. Activities must maintain certain records in order that the required information is readily available for reports preparation. In all cases prior to the submission of a report, the directive establishing the report should be consulted. This governing directive furnishes detailed information concerning preparation and submission of the report, including the exact data to be reported, the format or form to be used, the time of submission, and to whom it is to be submitted.

The 3-M System has brought about varied changes in reporting information relating to the inventory, logistics, readiness, and utilization of Navy aircraft. In fact, the Aircraft Accounting System has been changed to conform to 3-M System reporting.

Aircraft Accounting

Most of the information that is provided by the Aircraft Accounting System is accumulated or kept in production control. It is taken from Aircraft Logbooks, yellow sheets, and other forms provided for such recordkeeping. The AZ is normally responsible for recordkeeping; therefore, it is necessary for him to become thoroughly familiar with the reporting procedures required by the Aircraft Accounting System.

The purpose of the Aircraft Accounting System is to establish within the naval organization an aircraft accounting and statistical system of such scope and timeliness as to provide CNO, NavAirSysCom, and other users with sufficient information to plan, direct, and control the aviation element of the Navy; produce comprehensive aircraft inventory and logistics flow; furnish utilization and material readiness data; and to provide a consolidated statistical service to all activities concerned with naval aviation.

14265

Basically, the system is designed to provide all echelons concerned with naval aircraft with the following data: (1) Who has what aircraft, and in what condition and position in service life is the aircraft (this is inventory data); (2) just what was done, by whom, to aircraft (this is logistic data); and (3) just what was done, by whom, with aircraft, and how ready were the aircraft (this is utilization and readiness data).

The purpose of aircraft inventory, logistics, utilization, and readiness data is fundamentally for management. Management means deciding what is to be accomplished; directing the means (including funds) for doing it; commanding the use of the means; reviewing the whole operation to see how it could be done better; and generally learning and benefiting from experience. The capability for flight or actual flight of armed aircraft on a combat mission is the prime reason for naval aviation. Hence, aircraft is the prime element of naval aviation. Since the Aircraft Accounting System is the prime informational base for management of the aircraft element of naval aviation, accurate and complete data are of critical importance.

All data collected are used for specific purposes. The following are a few examples of uses made of the collected information.

1. Effective management of the maintenance effort requires information as to how many manhours by work center are expended on the various systems of each model. Since discrepancies and checks are usually related to utilization of the aircraft, flight and NOR data are necessary to manage a maintenance organization.

2. An exact knowledge of past flight performance must be known before future flying hour programs may be developed, justified to the Office of the Secretary of Defense and Congress, and finally funded.

3. The position of each aircraft in service tour must be known so that the number of PAR's, overhauls, and other rework operations coming due in coming fiscal years may be calculated, priced out, and budgeted for.

4. A centrally held knowledge of tour end date is necessary to the orderly replacement of aircraft returning for rework.

5. Justifying the purchase of new aircraft is also contingent on knowledge, at the Navy Department level, as to when each aircraft is due to complete its service life.

The term "aircraft," as used in the system, is limited to fixed and rotary wing aircraft, and includes drones (man carrying) and drone antisubmarine helicopter types. This excludes aerial targets (nonman carrying) and guided missiles.

Aircraft becomes subject to the system instantly upon acceptance by the Navy and remain so until stricken. Included in the system is the procedure for retirement and strike of Navy aircraft; that is, the means by which aircraft are officially removed from the Navy inventory. No aircraft can be so removed except in strict compliance with that procedure.

Reporting custodians are the initial source of all data used in the system. Controlling custodians are the users, monitors, and forwarders of this data. Each aircraft, at any point in time, is the accounting responsibility of one reporting and one controlling custodian. Generally, basic information is reported through the controlling custodian to CNO.

Figure 4-4 illustrates the flow of data generated by the Aircraft Accounting System for COMNAVAIRLANT, COMNAVAIRPAC, Naval Air Training Command (NATRA), and Naval Air Reserve Training Command (NART) reporting custodians. The data flow for reporting custodians of Naval Air Bases (NABS) and NavAirSysCom RDT&E is very similar to that illustrated in figure 4-4. The major differences are that XRAY data is submitted directly to CNO instead of first going to a command statistics unit and then to the Navy Information Center (NAVIC), and not ready hours and flight data are submitted by the base data services unit to CNO instead of first going to a command statistics unit and NAVIC.

The following elements of information are reported by each reporting custodian.

1. Whenever an aircraft is received, transferred, stricken, damaged, changed in status or undergoes any other reportable change, the cognizant reporting custodian initiates an OpNav XRAY message, in the prescribed format, reporting the action. Messages to the appropriate controlling custodian or to CNO are required on an asoccurring basis. As shown in figure 4-4 reporting custodians of COMNAVAIRLANT, COMNAVAIRPAC, NATRA, and NART submit XRAY data to the appropriate controlling custodian where it is keypunched and forwarded by the Automatic Transmission of Digital Information Network (AUTODIN) to CNO (NAVIC). After NAVIC processing, selected parts of the

AZ.10

Figure 4-4.—Aircraft Accounting System data flow diagram.

data, as required, are then directed to the Maintenance Support Office (MSO).

2. Whenever an aircraft accomplishes flight, the cognizant reporting custodian executes an ESD card describing the flight. Completed cards are forwarded daily to the data services unit where they are keypunched. Weekly, data services forwards, by mail, accumulated cards to the appropriate controlling custodian. The cards then move from the controlling custodian to CNO (NAVIC) to AUTODIN. After processing, flight information as required, is directed to MSO.

3. Whenever an aircraft "IN" a NOR reporting status (status codes A, B, or C, less C9) undergoes a period of not ready time, the reporting custodian executes an ESD card. Completed cards are forwarded daily to the data services unit where they are keypunched, the data summarized on a monthly basis, and then forwarded, by mail, to the appropriate controlling custodian, thence by AUTODIN to CNO (NAVIC).

In addition to this data, reporting custodians forward a copy of the Monthly Aircraft Readiness and Flight Report, ASD-3, as prepared by data

14267

services, directly to CNO (Op-511). The information contained in this report should equal the data forwarded through other channels by data services. This report provides CNO with a check on the efficiency of the regular transmission channel and further provides a backup in the event of failure of the system. It should be mailed within 1 working day of receipt from data services.

Regardless of who submits aircraft accounting data and its transmission path, all data reaches CNO and is used to construct a data bank maintained in NAVIC. NAVIC, by use of computers, is then able to provide information required by a long list of users including the MSO. NAVIC has the capability to summarize, extract, relate various elements, and print information in the format and detail specified by all activities having a legitimate need for Navy aircraft statistical data.

The reporting documents utilized in the Aircraft Accounting System are (1) the XRAY message and (2) the Equipment Statistical Data Card. The system also utilizes one record card, Aircraft Record "A" Card, OpNavForm 5442-9. A brief discussion of these documents and the "A" card is contained in the following paragraphs. A detailed discussion of "A" cards, XRAY reports, ESD cards, engine record cards, engine accounting reports, and configuration accounting is contained in AZ 3 & 2, NavPers 10391-A; therefore, these areas are not covered in detail in this training course. The AZ2 must be able to initiate "A" cards and engine record cards, and prepare XRAY and engine accounting reports. The AZ3 must be able to prepare ESD cards and make routine entries in engine record cards and "A" cards.

The senior AZ must supervise the completion of these tasks and perform review actions as required in order to insure that records are maintained and reports are prepared in accordance with existing directives. In order to properly supervise these tasks and perform the required review actions it is necessary for the senior AZ to be thoroughly familiar with each record and report mentioned. This may require additional study or at least a review of these areas in AZ 3 & 2.

AIRCRAFT RECORD "A" CARD.—The Aircraft Record "A" Card, properly used, provides valuable readily available information concerning each assigned aircraft. When an aircraft is received, an "A" card should be initiated. This consists of filling in the basic information or statistical data in the top sections of the card. XRAY transactions should be posted in the appropriate spaces on an as-occurring basis. Monthly and upon transfer, flight and landing data should be posted in the spaces provided. This information is taken from the flight section of the logbook. When an aircraft is transferred, appropriate spaces on the "A" card should be completed and the card retained for a minimum of 6 months. Blank cards are available through form supply channels, and procurement information is contained in NavSup Publication 2002, Section II.

XRAY REPORTS.—OpNav XRAY reports are used to furnish CNO and other activities information concerning what is happening to the many aircraft in the Navy inventory. All changes of aircraft reporting or controlling custody, model designation, status, etc., are reported daily by message to the controlling custodian or CNO, as appropriate. XRAY data is used to maintain a perpetual inventory of aircraft and reflects the latest custody, status, and other items about each aircraft.

The OpNav XRAY report is normally submitted prior to 1200 hours of the day following that in which any reportable actions occur and includes all actions involving the unit's aircraft which occurred during the hours 0001 to 2400 of the previous day.

The basic instructions pertaining to XRAY preparation, submission, etc., are contained in the Aircraft Accounting System, OpNav Instruction 5442.2 (Series). Controlling custodians have also issued instructions pertaining to XRAY reporting in their areas of control. These may vary slightly from the instructions contained in OpNav Instruction 5442.2 (Series) as controlling custodians may require their reporting custodians to submit additional items of data over and above OpNav Requirements, and controlling custodians are authorized to vary the mode of transmission, precedence, classification, and standard deadline. Controlling custodians may also require that XRAY reports be forwarded to additional information addressees. In all cases, either the appropriate controlling custodian's instruction or the OpNav Instruction should be consulted when preparing or reviewing an XRAY report.

Multiple XRAY actions may be reported with one message as long as the report involves one controlling custodian and one reporting custodian. The items of information for the first action are arranged vertically on the

14268

UNIT 2 - SELECTION, USE, AND CARE OF SEWING EQUIPMENT

Competencies

- Select appropriate sewing equipment and supplies for the job.
- Clean and maintain sewing equipment.
- Thread and operate a home sewing machine.
- Thread and operate an industrial sewing machine.
- Use sewing machine attachments.
- Make minor adjustments on sewing machine.
- Use sewing supplies economically.
- Store equipment and supplies neatly and orderly.
- Operate sewing equipment in a safe manner.

Motivating Procedure

Display a variety of industrial and home sewing machines commonly used in making alterations such as lockstitch, zigzag, hemmer, and buttonholer. Have class members examine machines and identify the use of each.

Learning Experiences

- Demonstrate the use and care of sewing machines that are not familiar to the trainees. Have students use unfamiliar machines until sufficient skill is developed for making professional alterations. Use score cards and stitching exercises to evaluate competencies of trainees.
- Invite a representative of a sewing machine company to discuss the importance of following the instruction book that accompanies most equipment. Also have the representative demonstrate the use of attachements for the machines.
- Show various pieces of small sewing equipment such as seam ripper, tracing wheel, and point turner or use illustrations from catalogs and magazines. Discuss characteristics and use of each item.
- Discuss procedures for the care of small equipment in relation to storing, sharpening, and maintaining. Have trainees check laboratory for examples of good storage.

Instructional Materials

- Wall charts on threading of machines

1424

left side of the page. Each additional action is arranged to the right of the first in a vertical column.

FLIGHT, READINESS, AND INVENTORY DATA COLLECTION AND REPORTING.—Reporting custodians use ESD cards to provide data services with three distinct categories of aircraft statistical data needed to produce machine reports or printouts displaying aircraft flight, readiness, and inventory data. Either prepunched/preprinted or handscribed ESD cards may be used in all areas of aircraft statistical data reporting.

The use of electric accounting machines has simplified the process of maintaining records and preparing reports used in aircraft readiness and utilization reporting. In fact, aircraft readiness and utilization data are prepared and submitted by data services.

Reporting custodians use ESD cards to report all flights by listing the flight purpose code, flying hours, and landings by type for each flight conducted by each assigned aircraft. This flight and landing data is extracted from Part D of the yellow sheet. In view of the requirements for reliable flight data for planning and budgeting, it is imperative that each flight be promptly and accurately reported.

Reporting custodians are accountable for each assigned aircraft for 24 hours per day. Each aircraft is considered to be operationally ready (OR) unless reported as not operationally ready (NOR). Readiness data reporting has application to only those assigned aircraft in status codes A, B, and C less C9. An aircraft is "IN" a NOR reporting status when it is in status codes A, B, or C less C9. NOR reporting is required only on aircraft "IN" a NOR reporting status. An aircraft is "OUT" of NOR reporting status when the status code is any other than those previously mentioned.

NOR data is reported on ESD cards; therefore, when an aircraft becomes NOR, for any reason, an ESD card must be initiated. An aircraft is NOR when it becomes known that a maintenance requirement exists which prevents the aircraft from performing its primary mission safely and completely. NOR time may be divided into two categories—not operationally ready maintenance (NORM) and not operationally ready supply (NORS).

After an ESD card reporting NOR data is initiated, it is held in production control until it is closed out. ESD cards reporting NOR data are closed out when the aircraft becomes OR, the aircraft becomes NOR for a different reason, or at the end of the day (2400 hours).

Each data services activity maintains a master file showing the complete aircraft inventory of each organization within the cognizance of that data services activity. This master file is used to prepare periodic machine reports and aircraft master lists. In order for data services to maintain this master file accurately, they must be notified by each reporting custodian of any changes in the aircraft inventory.

ESD cards are utilized to report inventory change data when an aircraft is gained into an activity's custody, an aircraft is lost from an activity's custody, or there is a change in the NOR reporting status of an aircraft (either into or out of NOR reporting status). The submission of an ESD card reporting inventory change data in no way relieves an activity of the responsibility for submission of an OpNav XRAY report.

Completed ESD cards reporting aircraft statistical data are delivered to the analysis division daily. Here they are checked for accuracy, completeness, etc., and forwarded to data services for processing. This processing includes keypunching the required data into decks of cards that are used by data services to produce machine reports. The original cards are then returned to the initiating activity where they are filed. Duplicate decks of cards and machine reports produced from these cards are forwarded to the controlling custodian and CNO, as appropriate, and are used to measure utilization effectiveness. Machine reports are used by both the local reporting custodian and higher level managers.

AIRCRAFT STATISTICAL DATA (ASD) REPORTS.—As previously stated, the completed ESD cards forwarded to data services provides the data required to produce machine reports concerning aircraft readiness, utilization, and inventory data. These reports are produced in two categories—standard reports and special reports.

Standard ASD reports are prepared for all activities to insure uniform reporting of basic aircraft statistical data within the Navy. These reports are prepared in a specified format on a recurring basis and designed for specific

14269

uses. There are four standard ASD reports.

Special ASD reports are those requested by individual activities on a one-time or continuing basis utilizing locally determined formats and containing selected elements of data. Any information known to exist in ASD files can be obtained in a special report. The contents of special reports depend upon the needs of the requesting activity. Any, or all standard reports may be prepared as special reports upon demand. This occasion could arise from a desire to produce certain reports for a specific period other than the normal reporting period.

A discussion of the standard ASD reports is contained in the following paragraphs.

The Aircraft Master List, ASD-00, is prepared by data services from ESD cards submitted during the month reporting inventory data. This report reflects the true aircraft inventory of an activity as of 0001 hours the first day of the month. It reflects aircraft gained into the inventory during the previous month and current NOR reporting status (IN/OUT) indicated by assigned aircraft hours listed under the applicable columns. Since this report indicates the true inventory picture at the beginning of each month, aircraft losses from inventory during the previous month are not listed. Each aircraft assigned to the reporting custodian is listed along with the activity organization and permanent unit codes, type equipment code and serial number of each aircraft, and the hours IN or OUT NOR reporting status.

The primary purpose of this report is to provide a means of verifying and correcting, when required, data contained in the local inventory data bank maintained by data services. Production control should check the report for accuracy and completeness by using local records of aircraft inventory change transactions which occurred during the previous month. Local methods of correcting the inventory data bank are normally established by the analysis division and data services. One suggested method of making corrections is by use of a marked up aircraft master list. Incorrect data should be lined out and the correct data inserted in red directly above the lined out entries. This corrected list is then forwarded via the analysis division to data services for corrective action as required.

The Daily Flight Report, ASD-1, is a detailed listing of all aircraft flight data submitted on ESD cards during the previous working day. The report may contain data for more than 1 day due to extended flights or flights on weekends or holidays. It indicates flight data collected during shipboard operations and shows landing data, departure and arrival times, date, and the duration and purpose of each flight conducted by each aircraft.

This report provides a means of verifying and correcting information in data services files. It also provides maintenance managers with a means of monitoring aircraft utilization on a daily basis and can be used as a measure of accomplishment of the previous day's schedule. This report is checked daily for accuracy and completeness by production control. Erroneous entries should be lined out and the correct data inserted, in red, directly above the lined out entry. After correction the report is forwarded via the analysis division to data services for correction of errors.

The Daily Aircraft Readiness Report, ASD-2, is a detailed listing of all aircraft NOR and inventory data submitted on ESD cards during the previous working day. Like the ASD-1, it may contain data for more than 1 day. The ASD-2 shows not ready conditions and inventory changes by bureau number. When an aircraft is reported as NOR more than once during the same day, the data for this aircraft is listed in the order the NOR times began.

This report provides a means of verifying and correcting information in data services files. It also provides maintenance managers with a means of monitoring operational readiness on a daily basis.

Maintenance managers use this report to identify specific problem areas that degrade the overall readiness condition. The nature of the problem areas identified may determine what action is necessary to improve readiness. Further, this report provides the means of identifying specific aircraft that detract from overall readiness, measuring the impact of scheduled maintenance, unscheduled maintenance, and supply support on readiness, identifying potential ready hours lost to the awaiting maintenance category, identifying systems or components that contribute to NOR conditions, and computing cumulative readiness rates. The report is checked daily for accuracy and completeness. In the event of errors, the erroneous data is corrected in the same manner as the ASD-1.

The Monthly Aircraft Readiness and Flight Report, ASD-3, is a summary of all flight and NOR ESD cards submitted during the reporting

14270

14269

period. It shows a summation, by bureau number and type equipment, of inventory status at the end of the month as indicated by the inventory identifier, hours assigned "IN" or "OUT" of a NOR reporting status, NOR hours by category, total flights and flight hours, and flights and flight hours during shipboard operations.

The report aids maintenance managers in their efforts to maintain optimum aircraft readiness and utilization. The format used lends itself to quick analysis of factors that affect aircraft readiness and utilization. This report provides a means to identify the operationally ready rate, not ready hours by reason, awaiting maintenance hours, aircraft lost to an "OUT" of a NOR reporting status, aircraft that continually account for a large portion of NOR hours, the hours flown by each aircraft, the average flight duration, and flights and hours accumulated during shipboard operations.

In addition to these standard reports, reporting custodians may request special reports from data services. It should be remembered that any information known to exist in ASD files can be obtained in the form of special reports. However, if the information desired is already available in another report, a special report should not be requested. Special reports should not be used indiscriminately because of the additional, and often excessive, workload imposed on data services personnel and machines.

AUDITING RECORDS.—At monthly intervals each reporting custodian receives a machine produced Monthly Inventory Accounting Report from CNO. This report is used to check and correct the central data bank. The report shows the current data bank picture of each aircraft in the unit's reporting custody during the month. The report lists all XRAY transactions processed on each aircraft during the month and also includes summary flight and NOR hours data.

The report is provided in triplicate (four copies to NATRA units) to the reporting custodian with an additional copy to the controlling custodian, for informational purposes. The reporting custodian must check the listing against local records for accuracy and completeness. If the data listed is accurate and correct, the report is so marked and returned to CNO (Op-511). If, however, the data is incorrect or incomplete, the reporting custodian must, within 2 working days of receipt, make such additions or changes on the copies as are required to reflect the true situation on each aircraft listed, and return one corrected copy, by fastest mail, to CNO (Op-511).

The corrected report is used to adjust the central data bank; therefore, every effort should be made to insure that any corrections or additions entered on the report be accurate. Figure 4-5 illustrates the format of the Monthly Inventory Accounting Report.

The following paragraphs discuss the format and some record check procedures.

The initial printed line on each bureau number includes the last previous XRAY transaction from a previous month. Flying hours (current month) and NOR hours on that line represent data for the period from the beginning of current month to either the instance of the next XRAY action or end of the current month. If the bureau number was subject to XRAY change during the current month, that change is also listed. Flying hours and NOR hours on this line represent data on the aircraft from the instance of this XRAY until the next action or month end, whichever occurs first.

The file of Aircraft Record "A" cards provides local record of XRAY changes on all assigned aircraft and can be used to verify the XRAY change aspects of the Monthly Inventory Accounting Report.

The Monthly Inventory Accounting Report contains flight-hour data on each aircraft since acceptance, in tour or period, and in current month. The report shows accumulated flight data for the intervals between the beginning of the month to the instance of the first XRAY report, between XRAY actions, and between the last XRAY trasaction and end of month. If the aircraft was in the unit's custody for the entire month, check the totals as of month end. On aircraft transferred during the month, check the totals as of date of transfer.

The Monthly Aircraft Readiness and Flight Report, ASD-3, provided to reporting custodians by data services, can be used to check the flight hours and NOR hours section of the Monthly Inventory Accounting Report.

Aircraft Engine Accounting

Aircraft are of little value to an operating squadron unless serviceable engines are available. In order to plan for the procurement of new engines and rework of engines in service, NavAirSysCom must be furnished information concerning the condition of engines in

Figure 4-5.—Monthly Inventory Accounting Report.

service, flying hours accumulated, and stage of progess that unserviceable engines have reached in the maintenance cycle. This is accomplished through the aircraft engine accounting system. This system is designed to provide timely aircraft engine management data to NavAirSysCom with the minimum of reporting effort on the part of reporting custodians.

Engines are the most expensive single item of support for an aircraft; therefore, close management control to reduce out-of-service time and the quantity of spare engines being procured is of prime importance. The current accounting system utilizes automatic data processing to provide NavAirSysCom timely engine data. NavAirSysCom maintains a master engine record file which contains the status, custody, and performance history of each aircraft engine in the active Navy inventory. This file is kept current by daily transaction reports forwarded by controlling custodians and NavAirSysCom FS custodians as changes occur in custody or status. The system also utilizes quarterly reports indicating engine hours since new or overhaul, as appropriate. These reports are used in the preparation of failure rate reports, utilized in overhaul schedule planning.

NavAirSysCom, through their representatives, assigns aircraft engines to the major operating commands. By using past failure rates, flying hours, scheduled commitments, etc., air type commanders are able to estimate, several months in advance, the number of engines required by their reporting custodians. With this information, NavAirSysCom can overhaul and rework unserviceable engines as well as procure new engines in order to meet the needs of the operating commands. Aircraft engines are assigned to the major operating commands and NavAirSysCom FS custodians in much the same manner as aircraft; that is, on a priority according to urgency of need.

Once in the custody of an aircraft engine controlling custodian, serviceable uninstalled engines are distributed to subordinate commands or pools. On occasions, engines are distributed direct to reporting custodians from the controlling custodian. Subordinate commands

14272

have the responsibility for further distribution and management control of engines located in their respective area. These subordinate commands monitor and initiate corrective action, as necessary, on all reports submitted by reporting custodians who receive engine support from their serviceable uninstalled engine pools.

Although aircraft engines are distributed to a subordinate command pool, they will probably be in the physical custody of supply or an Intermediate level maintenance activity. Engine buildup is a responsibility of Intermediate level maintenance activities, therefore, operating squadrons receive engines from their supporting Intermediate maintenance activity ready for installation.

NavAir Instruction 13700.1 (Series) prescribes reporting procedures for the Navy aircraft engine accounting system. These procedures are directed primarily to controlling custodians and NavAirSysCom FS custodians; therefore, controlling custodians have issued instructions concerning engine accounting in their areas of control. Instructions and directives promulgated by the appropriate controlling custodian should be consulted prior to the preparation or review of any aircraft engine accounting report.

The aircraft engine accounting system utilizes one record card and two reports. The reports are made either by message or on a form, depending on the appropriate controlling custodian's instructions. The record cards, Aircraft Engine Record, NavAir Form 13700/3, is used in engine accounting in much the same way as the Aircraft Record "A" Card is used in aircraft accounting. One card is maintained on each assigned engine. The record card provides a readily available record of the status, operating hours, number of overhauls, etc., on each assigned engine.

ENGINE TRANSACTION REPORT.—An Engine Transaction Report (ETR) is used to advise the controlling custodian of actions concerning the utilization or status code change of assigned engines. They are normally submitted once each work day covering all transactions occurring since the previous report. Some situations which require the submission of an ETR are as follows:

1. The installation of a serviceable uninstalled engine.
2. The removal of an engine and retention as a serviceable uninstalled engine.
3. The removal of an engine as an unserviceable engine.
4. The receipt and transfer of both installed and uninstalled engines.
5. The striking of an engine from the Navy inventory.

There are numerous other situations which require an ETR; however, the ones listed above are most often used by operating squadrons.

Reporting Field Designation Codes (RFDC's) are used to identify the items of engine data submitted in the required reports. These codes are used in all engine accounting reports to describe the items of information that are being transmitted. Certain RFDC's must be listed on every ETR. Others are used only in specified and seldom occurring transactions. The appropriate controlling custodian's instruction concerning engine accounting explains the proper use of RFDC's.

The numbering system for ETR's varies from one controlling custodian to another. One system used is to number them consecutively throughout the calendar year. Another system used is to number them sequentially by calendar quarter, beginning with a new series of numbers each quarter.

Unlike OpNav XRAY's, in which the data is reported in a vertical column, ETR data is submitted in a horizontal format. Each horizontal line in an ETR report details one engine transaction. They are submitted in this format to facilitate the direct keypunching operation required by the controlling custodian prior to forwarding the required data to the NavAirSysCom. The data in each column should be aligned with a straight margin on the left. Unless specified in the controlling custodian's instructions, an ETR should contain only information directly concerned with engine accounting.

If, after submitting an ETR, it is found that incorrect or incomplete data has been reported, a correction ETR should be prepared and submitted immediately. Correction ETR's are submitted by message or on a form, as appropriate, in the same basic format as regular reports. Correction reports are normally submitted as a two-line report—the first line reporting the same data as previously reported, and the second line reporting the correct data. A correction report may be made in conjunction with a regular report.

END-OF-QUARTER REPORT OF FLYING HOURS ON INSTALLED ENGINES.—The End-of-Quarter Report of Flying Hours on Installed Engines (EOQ report) is submitted as of 2400 hours on the last day of each calendar quarter.

14273

This report includes all engines in an installed status in the custody of the reporting custodian, regardless of location. Therefore, this includes engines in the reporting custodian's aircraft that are in pools, PAR, etc. The method of submission—speedletter, report form, etc.—may vary from one reporting custodian to another, depending on the instructions of the controlling custodian.

The type of engine reported governs the reporting quarters. Reciprocating and opposed type aircraft engines are reported as 2400 hours on 31 January, 30 April, 31 July, and 31 October. Gas turbine engines prefixed with the letters T and/or TF are reported as of 2400 hours on 28/29 February, 31 May, 31 August, and 30 November. Gas turbine engines prefixed with the letter J are reported as of 2400 hours on 31 March, 30 June, 30 September, and 31 December.

A completed EOQ report is very similar in appearance to an ETR, in fact the items of information are reported using the same RFDC's as an ETR uses. All engines should be listed by model in serial number order.

Configuration Reporting

It is the policy of the NavAirSysCom to maintain naval aircraft and related equipment in a configuration which provides the optimum conditions of safety and material and operational readiness. To insure that this policy is carried out it is necessary that operational aircraft and related equipment be maintained in the latest approved configuration. Safety and operational readiness are greatly dependent on the timely compliance with directives received and the reporting of current aircraft configuration.

The Aeronautical Technical Directives Requirements Program, established by NavAirSysCom, is a system for recording by specific aircraft the applicability and incorporated/not incorporated data for all technical directives that require a logbook entry. This program encompasses all aircraft in the naval operating inventory. The listings produced from this data provide managers with statistical information in many areas of the NAMP. This data provides management with assistance in making informed decisions concerning the approval of additional changes by NavAirSysCom, procurement and distribution of change kits, assignment of aircraft, projecting workload requirements for all levels of aircraft maintenance, and evaluation of aircraft readiness and mission capability.

The basic sources of information for aircraft configuration data are those technical directives which require a logbook entry and are issued by NavAirSysCom.

For proper control of the system, NavAirSysCom has established three major control points. NavAirSysComRep-Lant/Pac have been assigned as control points for aircraft under the cognizance of COMNAVAIRLANT and COMNAVAIRPAC and other commands within the cognizant areas. NavAirSysComRep NavAirTraCom is the control point for aircraft under the cognizance of the Chief of Naval Air Training and the Chief of Naval Air Reserve Training and other commands within the cognizant area. These control points have issued instructions concerning configuration reporting in their areas of control. They determine the configuration status of each aircraft within their cognizant area and forward this data to the Naval Air Technical Services Facility (NATSF) where it is consolidated and distributed as required. NATSF maintains a master data bank concerning aircraft configuration that is updated by the reports submitted by reporting custodians.

There are four lists used in the program. These lists provide specific information regarding the applicability and incorporation status of effective technical directives. Some of these lists have little or no application at the reporting custodian level and are not discussed in this training course.

The Aeronautical Technical Directives Not-Incorporated List 2, issued by the appropriate NavAirSysComRep is the one of most concern to the AZ. This is an IBM listing, published monthly, by bureau number, containing all airframe changes, bulletins, etc., that have not been incorporated in a specific aircraft. It is normally issued during the first week of the month. There is a separate listing for each model aircraft which is subdivided into listings for each bureau number assigned. The listing may contain directives that are not required by a particular custodian but may be required by another custodian in the event of a transfer. Therefore, those directives listed that are applicable but not required will remain on the listing.

Two copies of this list are normally received. After making the necessary entries on these copies, one copy is returned to the issuing activity and the other is retained by the reporting custodian. When an aircraft is

14274

transferred, the current List 2 should be inserted in the Aircraft Logbook prior to transfer.

In completing the listing, compare it with the appropriate part of the technical directives section of the Aircraft Logbook. If a listed directive has been completely incorporated, a red X is placed in the first (asterisk) column. If a particular directive number is listed and has been marked NA in the Aircraft Logbook, an amplifying reason should be given in the REMARKS column on List 2.

This may require research and investigation to validate the entry. If any directive, requiring a logbook entry, has been incorporated since the last report but is omitted from the listing, the directive number and code should be written in the appropriate columns in numerical order and the directive indicated as being incorporated. Any known directive, which is not incorporated, and requires a logbook entry, but is omitted from the listing, should be written in at the bottom of the listing.

The Aeronautical Technical Directives Incorporated Data by Bureau/Serial Number List 4 is a list of affected technical directives applicable to a specific bureau number and reported as incorporated. This listing is received semiannually and contains those technical directives reported as being incorporated on List 2. It is used in the Aircraft Logbook as a record of technical directive compliance. No entries are normally made on this listing by the reporting custodian.

Review of Aircraft Logs, Related Records, and Reports

Detailed discussion of the Aircraft Logbook and the uses of its many forms is contained in the current edition of AZ 3 & 2; therefore, additional coverage is not appropriate in this training course.

Although all AZ's should know how to properly maintain aircraft logs and related records, senior AZ's must be proficient in this task. They will, in most cases, be the supervisor and the person responsible for accurate logs and records maintenance as well as overall supervision of the production control office. The first sections of chapter 3 should be studied carefully as these sections discuss several aspects of supervision. In addition, senior AZ's should possess the "know how" to review all records maintained and all reports submitted, for accuracy and completeness. Basically, this consists of being familiar with the governing instruction requiring a record to be maintained or a report to be submitted, and then following the instructions it contains in detail.

Most of the entries made in aircraft logs and related records, as well as report typing, are accomplished by lower rated personnel; therefore, senior AZ's have numerous review actions. Reports prepared by lower rated personnel should be reviewed by the senior AZ for accuracy, proper format, etc. Also, periodic spot checks should be made of records which furnish information for reports.

Periodically, the complete Aircraft Logbook should be reviewed. One suggested way to accomplish this in conjunction with the screening process accomplished on the logbooks prior to scheduled calendar inspections. In addition to this, the Aeronautical Equipment Service Record or Accessory and Component Service Record should be carefully reviewed, for components replaced, after necessary entries are made and prior to their insertion into the applicable logbook. By following this system, errors found can be corrected at an early stage, thus eliminating duplication of effort. When conducting this type of review particular attention should be directed to the separator pages which precede the various sections of the logbook. These separator pages contain instructions for completion of the various logbook forms as well as illustrations showing sample entries.

Other review actions are required on all reports prepared for submission to higher authority. Reports are required in order to furnish activities various types of information. This information is used by managers in all phases of naval aviation; therefore, it is of utmost importance that all reports submitted be accurate and complete. After typing and prior to transmission, all reports should be carefully reviewed to ascertain that only correct information has been listed. Reports should be compared with the samples illustrated in the governing instruction to insure that the correct format has been used.

In addition to the review actions previously discussed, senior AZ's assigned to production control of an Organizational level maintenance activity are responsible for insuring that aircraft status boards are correct and maintained up-to-date. Normally, the master aircraft status board is maintained in production control. Additional boards may be maintained in the operations department or the squadron duty office,

14275

depending upon the requirements of each particular activity. The main purpose of an aircraft status board is to display pertinent information so that personnel having a need to know can quickly ascertain the essential facts concerning aircraft status. This purpose is defeated unless status boards are maintained current. Although remote status boards, if used, may not contain detailed aircraft status information, as does the master board, they should portray an overall "up"-"down" picture of assigned aircraft.

The master board should be updated each morning and then throughout the day as maintenance actions and flights involving status changes occur. Monthly, those entries showing accumulated airframe or engine times should be verified with the logbooks. In order to monitor the operating time of certain major components (engines, props, etc.) nearing their scheduled removal time, the hours listed on the status board may be entered or encircled in red during the final 10 percent of their replacement interval. This serves as a caution sign and assists in scheduling and planning actions.

Hourly as discrepancies or other actions affecting aircraft status occur, this information is posted on the status board. Likewise, discrepancies listed should be removed, once maintenance actions on these discrepancies are completed. Production control is normally first to receive word of the completion of maintenance tasks or other actions affecting aircraft status; therefore, the master status board should be updated to show the true picture of aircraft status at all times.

Production control personnel also maintain Organizational Maintenance Control Registers. These registers assist in controlling the maintenance efforts.

WORK REQUEST

NavAir Form 4710/6 (fig. 4-6) has been provided for use as a Work Request Form. The Work Request is originated by a maintenance activity when requesting specific work beyond its capability from a supported activity. This request form is utilized for the following:

1. Requesting check, test, and servicing of items removed from an aircraft or equipment for scheduled maintenance. When requesting work of this nature the request is prepared in duplicate and additional information is required. The job control or request number, bureau or serial number of the aircraft or equipment from which the item was removed, type equipment code, and nomenclature and serial number of items to be checked are listed in addition to the information required by the form.

2. When requesting work or assistance which is beyond the requesting activity's capability and does not involve repair of aeronautical material. When used for this purpose, requests are prepared and processed in accordance with local directives.

3. To induct components into the Intermediate maintenance activity from supply for technical directive compliance, updating, and check and test. Under these conditions, the request is originated by the supply activity.

4. To induct items not part of an aircraft or support equipment that require check, test, servicing, or minor repair. For example, pilot's personal equipment, oxygen masks, life preservers, etc.

The request form is divided into sections. The top section is completed by the supported activity and the bottom section by the supporting activity. Detailed instructions for preparation of the Work Request are printed on the form. Preparation of the form is discussed in the following paragraphs.

The name of the activity requested to perform the work is entered on the "To" line. To the right, and on the same line, the date of the request is entered. On the next line is entered the name of the requesting activity and the work request number. The numbering system is usually established by local policy. One suggested way is to start at the beginning of each calendar year and number them consecutively. For example, 1-68, 2-68, etc.

The justification for the work requested is entered in the next space. Usually, the justification will be a notation that the work requested is beyond the capability of the requesting activity.

The next space is completed to show the physical location of the job. In most cases involving work on small items, the items are delivered to the supporting activity.

The name and telephone number of the person, to be contacted in case additional information concerning the request is required, is entered on the next line. Naturally, this should be the name of the one person knowing the most about the requested work. Opposite this entry the requested completion date should be entered. The date entered should be realistic so the

14276

WORK REQUEST
NAVAIR FORM 4710/6

TO: AMD Moffett Field	DATE: 17 June 1968
ORIGINATING ACTIVITY: VP-9	WORK REQUEST NO.: 21-68

JUSTIFICATION FOR WORK REQUEST

Beyond capability of Organizational maintenance activity.

LOCATION OF JOB
Will be delivered to AMD hangar.

FOR FURTHER INFORMATION CONTACT (Name and telephone number): L. E. Drake, AFCM, Ext. 364	REQUESTED COMPLETION DATE: 21 June 1968

WORK REQUESTED
(Give complete, accurate and detailed description of desired work. Attach sketch if necessary.)

Incorporate P-3 Airframe Change 114 Part I in P-3A BUNO 150511
(Copy of change attached.)

REQUESTING ACTIVITY WILL FURNISH MATERIAL AS FOLLOWS: V50-1P3-114	REQUESTING ACTIVITY WILL FURNISH ASSISTANCE AS FOLLOWS: 2 men (1 AE3 and 1 AE2)

SIGNATURE (Maintenance Officer of Supported Activity) G. H. Cooper

14277

supporting activity can assign the correct priority for the completion of the requested work.

In the next space is entered a complete, accurate, and detailed description of the work requested. Any sketches or directives to accompany the request should be listed in this space.

The nomenclature and stock number of any material furnished by the requesting activity is entered in the next space. To the right of this space is entered any assistance which will be furnished by the requesting activity for completion of the job.

The maintenance officer of the requesting activity signs the request in the space provided for this purpose.

The remainder of the form is used by the supporting activity to indicate action taken on the request.

After receipt and review the request is approved or disapproved by entering X in the appropriate block. If the request is disapproved, the reason for such action is entered in the space provided. The form is signed by the maintenance officer of the supporting activity. On the last line of the form is entered the date on which the work requested is started, the date on which the work is completed, the date the requesting activity is notified of its completion, and the production control number (PCN) assigned to the job.

If the requested work is beyond the capability of the supporting activity, the request may be passed to an activity having a higher level of capability for completion.

INTERMEDIATE MAINTENANCE

Intermediate maintenance activities (IMA) are primarily concerned with support of operating units within a designated area or at a particular base or station. The tasks performed by production control personnel of an IMA are somewhat related to those performed at an Organizational level activity. Some of the same records and reports are required as well as certain planning and scheduling actions. Some of the specific functions of the IMA production control are as follows:

1. Exercise direct supervision over the production divisions to insure conformance to established policies.
2. Coordinate the actions of the production divisions to insure prompt movement of components, parts, and material.
3. Maintain liaison with supported activities to provide maximum utilization of the IMA productive capacity and to insure that productive efforts are compatible with workload requirements.
4. Insure compliance with all technical directives by cognizant divisions.
5. Monitor personnel, support equipment, and material utilization of production divisions.
6. Plan and schedule workload as necessary to carry out all commitments.
7. Assign work to the production divisions, including the assignment of priorities and completion times.
8. Maintain master files of outstanding/completed source documents and maintenance instructions.
9. Maintain Aeronautical Equipment Service Records and Accessory and Component Service Records.

As head of production control, the Maintenance/Material Control Officer is charged with the responsibility for accomplishment of these specific functions in addition to the overall responsibility for the production efforts of the department. He is assisted in meeting assigned responsibilities by the Production Control Chief.

With a few exceptions, all Intermediate maintenance activities no longer are reporting custodians of aircraft. This was brought about by the implementation of the three level maintenance concept. Therefore, numerous records, reports, and scheduling actions required by Organizational activities are not required by the IMA.

Since the IMA is primarily concerned with component repair and support of operating units, production control is involved with many components daily. It is neither practical nor desirable to attempt to control each component inducted into the activity from a central production control area if facilities are widely disbursed and hundreds of components are involved daily. Under these conditions, management is accomplished by the delegation of certain production control functions to selected production divisions.

Divisions so designated exercise direct control of the production efforts of assigned work centers, are responsible to production control for the production efforts of the assigned work centers, assign production control numbers to work assigned to work centers, schedule components into work centers, and assign priorities as directed by production control. Even though certain production control functions are delegated to production divisions, production

14278

- Large and small equipment used for making alterations such as industrial and home sewing machines and marking, measuring, cutting, and ripping equipment
- Stitching exercises
- Machine instruction books
- Examples of clothes with safety features
- Score cards on machine use

1425

control always retains the functions of satisfying special requirements of the Supply Support Center, reassignment of support equipment, material or personnel from one work area to another, and placing special priority assignments on the production division efforts.

Production control holds meetings, at frequent intervals, with production and material control personnel to discuss production efforts and problem areas. However, any factors affecting the production effort should be relayed immediately to production control.

A monthly maintenance planning meeting is convened by the IMA. This meeting is attended by representatives of all supported activities on scene at the time of the meeting. The purpose of this meeting is to provide the necessary planning and coordination to improve the overall maintenance program. Supported maintenance representatives discuss the quantity and types of support required, including the schedule of components due for check and test. All factors affecting the anticipated Intermediate maintenance workload are presented by supported representatives.

From the information gathered at this meeting, and other known support requirements, a monthly maintenance plan is published for use by the IMA production divisions. This plan includes a projected schedule of items to be inducted for check and test, anticipated changes in the Intermediate maintenance workload due to operational commitments of supported activities, and other known or anticipated factors affecting the production effort of Intermediate level maintenance.

Due to the fact that Intermediate level maintenance activities are not reporting custodians of aircraft, they are not involved in aircraft accounting and reporting procedures. However, they are responsible for aircraft engine buildup, repair, etc., and therefore, must maintain Aeronautical Equipment Service Records as well as complying with the current instructions concerning engine accounting. Production control should insure that these records are accurately maintained and any required reports properly prepared. Numerous components received into the IMA have Accessory and Component Service Records. Changes, bulletins, repairs, etc., completed on these components should be accurately recorded on the record cards.

Intermediate maintenance activities maintain large quantities of aircraft maintenance support equipment (AMSE). Much of this equipment utilizes maintenance and custody records; therefore, production control personnel must maintain these records. Production control personnel must also initiate AMSE data cards to report AMSE inventory changes, status code changes, NOR time, and utilization.

In addition to the many scheduling actions required to induct components into the production divisions, production control receives work requests from supported units requesting various maintenance tasks. These requests require prompt review in order that the necessary action may be initiated for their completion.

DEPOT MAINTENANCE

It is neither practicable nor possible to discuss, in this training course, all the numerous maintenance tasks performed by Depot level maintenance activities. Likewise, due to their size the organization of these activities is of little concern to the AZ.

In general, these activities have the capability to perform all levels of maintenance on assigned types and models of aircraft, powerplants, and aeronautical equipment. The utilization of this capability is limited, by Navy policy, to performance of only specific tasks which cannot be performed properly, economically, or expeditiously by lower level maintenance activities.

The utilization of commercial or intraservice facilities is limited to the terms of the contract or agreement describing the specific tasks to be performed. These agreements and contracts are based on the same policy as that used in determining the assignment of work to Naval Air Rework Facilities (NARF's).

Guidance for utilization of services of Depot maintenance activities and assistance in determining specific action to be taken can be obtained from NavAirSysCom Hq, NavAirSysComReps, air type commanders, their subordinate commands, or the Depot maintenance activities themselves.

Depot maintenance includes overhaul, modification, and major repair of aircraft and related aeronautical equipments, manufacture of certain aeronautical parts, and the manufacture of kits for the accomplishment of aircraft and equipment modifications. This type of maintenance is usually performed in large industrial type facilities. These facilities are either military or commercial.

14279

Frequently, Organizational and Intermediate maintenance activities require the assistance of Depot activities to complete maintenance tasks. The following sections contain information on some of the functions performed at Depot level activities which are of concern to the senior AZ.

AIRCRAFT REWORK

Certain facts pertaining to the service life of an aircraft are known at the time of procurement. One of these is that after a certain number of accumulated flying hours or calendar months the aircraft will go to a Depot level maintenance activity for standard rework. Between these standard rework periods, aircraft may receive special rework.

Aircraft rework is categorized as either standard or special rework. Standard rework includes overhaul, progressive maintenance, airline maintenance, and progressive aircraft rework (PAR). These types of rework are required at the completion of a specified tour or period of service. The rework performed is of sufficient depth to provide a finished product that is capable of safe completion of the next tour of service. Special rework includes conversion, in-service repair, modernization, modification, and damage repair at the overhaul level. These types of rework are performed as required and to the degree necessary to meet the requirements of the specific type of rework involved.

Rework is the restoration or added work performed on an aircraft, aircraft equipment, etc., by aircraft industrial establishments or contractors' plants. A rework process extends from the time some of the work is started until all of the work has been completed, including temporary interruptions in direct labor, work evaluation and test, and the correction of discrepancies determined thereby.

The word "Standard" as used with rework does not imply standardization of the work process involved. It only identifies those particular processes which are basic to the standard service life of Navy aircraft as distinct from those processes which are not. For example, overhaul is standard rework because the standard service life of Navy aircraft involves alternating service tours and overhauls; it does not mean that all overhauls follow the same fixed specifications of work to be done. Actually, each aircraft undergoing standard rework is reworked (under nonstandard work specifications) only to the extent necessary to meet certain standard end product specifications.

NavAirSysCom establishes a schedule for standard aircraft rework completions by model and type of rework for each activity performing Depot maintenance. Damage repairs, to overhaul level, are included in this schedule—in-service repairs are not. The schedule is determined by the requirements of the operating forces, as established by CNO, and is constructed within the limitations of aircraft availability for rework, plant capacity and capability, and funds available. Specific inductions, by bureau number, are established through coordination between controlling custodians, NavAirSysComReps, and the Depot maintenance activity concerned.

Special Rework

Special rework is the work done to aircraft, aircraft equipment, and aircraft support equipment to improve or change their capability to perform specific missions or functions by replacement, removal, addition, alteration, or repair of parts of equipment of the aircraft, and without particular regard to the position in standard service life. Special rework is divided into several processes as discussed in the following paragraphs.

Conversion is special rework the accomplishment of which alters the basic characteristics of the aircraft to such an extent as to effect a change in any part of the model designation. If the rework process includes both conversion and overhaul, the proper term is standard rework, overhaul-conversion. If the process includes both conversion and modernization, the proper special rework term is modernization-conversion.

In-service repair is repair by NavAirSysCom FS activities of aircraft damaged beyond the repair capacity of controlling custodian maintenance activities. Controlling custody remains unchanged between or during the changes in physical custody. In-service repair is special rework, and the aircraft undergoes the entire rework process of the NavAirSysCom FS activity concerned, unless specific exceptions are requested by the controlling custodian.

Modernization is special rework performed on new or newly overhauled aircraft withdrawn from storage. It includes incorporation of applicable changes and bulletins, installation of

14280

acceptable accessories, and flight testing. It also applies to aircraft which do not complete rework due to equipment shortages and other reasons and which are subsequently returned to the rework process for completion. Modernization-conversion is a special rework process involving both modernization and conversion.

Modification is special rework accomplished by NARF's on new production aircraft and aircraft in the controlling custody of the operating commands. It includes only the incorporation of changes and bulletins and the correction of discrepancies as required in the directive authorizing the work to be performed. In effect, the only basic difference between modernization and modification is that modernization applies to aircraft withdrawn from storage while modification does not.

Repair is special rework accomplished to correct material damage and to restore the aircraft to the equivalent material condition which it had prior to the damage. If the rework process includes a combination of either repair and overhaul or overhaul-conversion, the type of rework performed is overhaul or overhaul-conversion, respectively, not repair. Aircraft may be in the controlling custody of either an operating command or NavAirSysCom FS while undergoing repair.

Standard Rework

Standard rework is the work performed on aircraft at NARF's or contractors' plants after (and as a result of) completion of a prescribed period of operational service. The end product specifications of the work permits aircraft to serve a full standard period of operational service before undergoing the rework again. Standard rework is divided into several processes as discussed in the following paragraphs.

Overhaul is standard rework performed on aircraft subject to standard service tours. The scope of the rework includes disassembly sufficient to inspect all the operating components and the basic aircraft structure; followed by repair, replacement, or servicing as necessary; followed by reassembly and flight test. Upon completion of the rework process, aircraft are capable of performing their intended mission for a full service tour. An overhaul is given either upon completion of a given period of time in a standard service tour or upon receiving damage of a severity to warrant the process.

PAR is standard rework performed upon accumulation of a predetermined number of calendar months. In certain cases, accumulation of a predetermined number of flying hours may subject aircraft to the PAR process. Aircraft subject to PAR do not receive a planned overhaul during their service life.

The work performed includes modification/modernization, planned rework to insure compliance with NavAirSysCom functional and safety standards for the prescribed service period, and correction of maintenance deficiencies or discrepancies beyond the ability and/or capacity of the operating units. Most Navy aircraft are reworked under the PAR concept.

PAR-conversion refers to a rework process, involving both PAR and conversion. Likewise, PAR-modernization and PAR-modification refer to standard rework processes involving PAR and modernization/modification, respectively.

Progressive maintenance is standard rework done in a consecutive series of a predetermined number of partial overhaul processes, each with different specifications of work to be done, the composite of which represents a complete overhaul by incremental stages. Aircraft subject to progressive maintenance progress through a series of cycles each of which is composed of a given number of operating periods followed, in succession, by a like number of progressive maintenance periods.

A cycle begins with the first operating and ends upon completion of the last progressive maintenance period specified for the cycle. An operating period begins when the controlling custody of an aircraft changes from NavAirSysCom FS to an operating command and ends when the reverse occurs. The number of the operating period is the same as the number of the progressive maintenance period which immediately follows the completion of the operating period.

An operating period is terminated after a given number of flying hours or a given number of calendar months, whichever occurs first. Aircraft are not operated after termination of an operating period unless an extension has been authorized. The progressive maintenance period is the time while the aircraft is in the controlling custody of NavAirSysCom FS for progressive maintenance. NavAirSysCom specifies the particulars of work to be accomplished during each successive progressive maintenance period. Each progressive maintenance period accomplishes a partial overhaul. When

14281

a cycle is complete, an aircraft has had the equivalent of one complete overhaul.

Airline maintenance is a form of progressive maintenance distinguished by short operating and rework periods. The aircraft controlling and reporting custodian remains unchanged during or between operating and rework periods.

Analytical rework is a systematic procedure for determining and maintaining reliability through selective equipment sampling and engineering evaluation. This type of rework is normally concerned with particular aircraft parts or components. Analytical rework is performed in selected areas in each aircraft inducted into PAR.

POWERPLANT REWORK

Depot level maintenance activities perform powerplant rework, which consists of both overhaul and repair of engines. Engines processed through overhaul become ready-for-issue and capable of operating for the complete operating interval prescribed. Overhauled engines revert to zero time since overhaul. Engines processed through repair are suitable for continued operation to the prescribed interval. Repaired engines retain time accumulated since last overhaul or since new if never overhauled.

NavAirSysCom establishes rework requirements for engines, by model and activity, for each quarter in terms of completions. The requirements are calculated to support the flying hour program established by CNO within the limitations of backlog availability, plant capacity, and funds. Existing instructions provide for return of unserviceable engines to the designated overhaul point. Specific scheduling and distribution are controlled by the cognizant NavAirSysComRep.

AERONAUTICAL SPARES AND COMPONENT REWORK

Individual Depot and commercial maintenance activities are assigned repair and overhaul cognizance for specific aeronautical spares and components. Spares and components requiring repair or overhaul, beyond the scope of Intermediate maintenance activities, are returned to these designated overhaul points in accordance with current ASO instructions.

Intermediate maintenance activities are assigned screening and repair functions to process such items for their assigned areas, to return to service repairable items, and eliminate unnecessary overhaul and shipping delay and cost. ASO establishes requirements for rework of components based on usage figures and planned aircraft operating programs. NavAirSysComReps direct the Depot or commercial maintenance activity to implement schedules to meet these requirements.

It should be remembered that material cannot be reworked that is not available and future requirements cannot be predicted from incorrect usage data. Therefore, everyone concerned should try to insure expeditious processing of material to be returned for rework and complete reporting of all items used.

CUSTOMER SERVICE

The high cost and complexity of aeronautical material and the need for maximum use of limited assets made necessary the development of efficient procedures for the expeditious repair of items causing NORS conditions. Also, the development of capability to perform aircraft rework, engine rework, and component rework has resulted in providing the Navy a source for "call" type rework or repair to meet unscheduled requirements. Consequently, Depot activities manufacture certain items to satisfy replacement needs for operating units. They also perform rework of specific items urgently needed to meet immediate demands where other sources are unable to provide support. This usually applies to parts not available or not in stock in supply channels. This type of support is classified as Customer Service. The customer service facilities at all Depot activities contribute substantially to satisfy specific maintenance requirements of Organizational and Intermediate activities.

Customer service includes NARF professional services; immediate check, test, and/or repair of operating and maintenance activities' aeronautical materials; processing of material to relieve NORS conditions; and technician services beyond the capabilities of aviation units.

Customer service was instituted to provide direct support to fleet aviation units in their technical and material maintenance problems. This service is extended to all other aviation operating and maintenance activities and units. Customer service supplements, not replaces, existing supply and Intermediate maintenance procedures.

IRSAI 14282

The following types of support are included in the customer service program:

1. Professional, including engineering and consultation services on aeronautical, electrical, and radio-radar materials and support equipment. Also advisory and consultation services on maintenance operation, minor repairs, and assistance in the indoctrination of personnel on new equipment with which the NARF has had experience.
2. Aircraft weight and balance services.
3. Processing of aeronautical materials and equipment. This includes inspection, bench testing, and functional checking of various accessories and components, provided the operating units or its supporting maintenance activity does not have the necessary testing equipment or other capability.
4. Heat treatment, Magnaflux, electroplating, battery charging, etc.
5. Machinist services to remove stripped or broken studs, spark plugs, helicoils, etc.
6. Chemical, physical, and metallurgical laboratory testing requirements.
7. Preservation of engines.
8. Requirements for dry air for canned engines, accessories, and equipment.

The various NARF's, in conjunction with major commands, operating NavAirSysComReps, and subordinate area commands have promulgated instructions concerning the availability and use of customer services in their areas. These instructions specify the procedures to be followed and the request form to be used when requesting customer service support. Therefore, no attempt is made in this training course to discuss the completion of customer service request forms. Some activities may use the Work Request form, discussed earlier in this chapter, for this purpose.

Organizational level activities normally submit requests for work or assistance concerning NOR conditions to their supporting Intermediate activity. If the work or assistance requested is justifiable, and cannot be provided by the supporting activity, then the request is forwarded to customer service of the appropriate Depot level facility for action.

Because the capacity for customer service type of support is severely limited by manpower, material, and funds, activities requesting customer service should insure that normal support channels, including the capability of lower levels of maintenance in repair or manufacturing, have been exhausted prior to requesting assistance from Depot facilities.

On the other hand, because the capability of each Depot activity is so varied and extensive, it is better to be mistaken on the side of requesting service for which no capability exists than to assume noncapability when the service could be performed.

ENGINEERING SERVICES AND FIELD TEAMS

Depot maintenance activities provide operating squadrons and maintenance activities additional support in the form of engineering services and field teams. A brief discussion of this support is contained in the following paragraphs.

Depot activities assigned the prime responsibility for manufacture or rework of specific equipments maintain engineering staffs capable of solving problems not discussed or provided for in manuals such as Overhaul Instructions or Structural Repair Manuals. Assistance is provided in prototyping special installations or changes. These types of engineering services are available to all maintenance activities on request. Specific engineering assistance can also be obtained from NavAirSysComReps for items manufactured by concerns whose contracts are under their cognizance. Such assistance is obtained by application to the cognizant NavAirSysComRep.

Each NARF has been provided a limited amount of money for the establishment of field team service for special maintenance functions. Scheduling for the utilization of these field teams is done by the cognizant NavAirSysComRep and coordinated by the type commander. This service is usually restricted to incorporation of airframe changes and engineering fixes affecting safety, whose complexity or requirement for special tooling precludes incorporation by lower levels of maintenance.

To conserve the time of field teams so that maximum effort is spent on work which cannot be performed by lower levels of maintenance, field teams should be requested to perform only those maintenance tasks which cannot be completed by Organizational or Intermediate maintenance activities. Specific instructions issued by type commanders provide procedures for requesting field team service.

14283

Chapter 5

DATA SERVICES AND MAINTENANCE DATA ANALYSIS

Recordkeeping, the preparation of reports, and the maintenance of related data have always been vital functions in the administration of naval aviation. Until recently, most of these functions were performed manually. Equipped with a pencil, a typewriter, and an adding machine, personnel performing clerical duties recorded the expenditure of supplies and money, maintained aircraft readiness and flight records, and prepared many different reports by manually arranging documents and typing long lists of information or adding many sets of numbers.

With the introduction of more complex weapons systems and the growth of the Navy came the requirements for more records to be maintained and many additional reports to be prepared. Data processing systems were developed and adopted to perform many of these functions by mechanical means. By transferring information contained on source documents onto a punched card, a means is provided for mechanically arranging information in any desired sequence, maintaining files, and preparing reports automatically, accurately, and at a high rate of speed. The principle of mechanical recordkeeping is based on the punched card.

Data processing is a series of planned operations upon information to produce a desired result. The procedures and devices used in the data processing routine constitute a data processing system. The development and installation of data processing systems utilizing data processing equipment provide an effective management tool in gathering, compiling, balancing, recording, and reporting information.

Automatic data processing systems comprise all manual, mechanical, electrical, and electronic data processes required in accomplishing the functions stated above. Such systems are built around a group of machines or devices which permit handling much of the data processing routine automatically. These machines and devices generally are classified either as Electric Accounting Machines (EAM) or Electronic Data Processing Systems (EDPS).

Electric accounting machines are designed so that each machine, as a general rule, is used separately to perform one specific processing operation as directed by control panel wiring. Punched cards are the primary medium for supplying source data for processing and manipulation.

This type of equipment is used by most data service activities in processing data collected by aviation maintenance activities in accordance with the Navy Maintenance and Material Management (3-M) System.

To assist management, certain analysis functions are performed on collected data. This is properly the responsibility of the analysis division. Specially trained senior AZ's are normally assigned to this division of Organizational and Intermediate maintenance activities. Most analysts receive this special training by attending the Aviation Maintenance Data Analysis Course, Class C, located at the Naval Air Technical Training Center, NAS, Memphis, Tennessee.

This chapter discusses some of the aspects of data analysis and provides information on data service activities and their responsibilities to the Aviation 3-M System.

DATA SERVICES

Data Services is the functional unit that converts documented data into data processing machine records and utilizes these records to produce (1) machine reports for maintenance and material management at the Organizational and Intermediate levels; (2) machine produced aids that are used by maintenance personnel to report expended manhours and material; and (3) provide a Central Data Processing

68S4284

Facility with a duplication of that portion of the data that is required for maintenance and material management above the local level and inclusion in a Navy Maintenance Data bank.

In regard to the manhour accounting system, data services is responsible for the accurate preparation of prepunched/preprinted cards and the timely preparation of required reports. They also perform the following functions:

1. Maintain a master roster deck by organization, work center, and name of each person assigned to the various work centers.
2. Forward a master roster listing to the analysis division for ultimate distribution to the various work centers. This roster is kept current at all times by the work center supervisor and analysis division. Data services produces a new roster, reflecting the previous month's changes, and forwards it to the analysis division not later than the second working day of the reporting period.
3. Furnish a daily labor exception listing for each work center.
4. Forward the monthly actual labor utilization reports for each work center concerned.
5. In coordination with the analysis division, prepare additional manhour reports as required.

The responsibilities of data services in maintenance data reporting are closely related to those previously discussed. In addition to the responsibility for processing collected data and for accurate and timely preparation of reports, data services also prepares prepunched/preprinted SAF's, verifies the source document count on all document control forms in order to insure that no documents are lost, and assists the analysis division in developing procedures for special reports.

Data services is also responsible for processing both aircraft and aviation maintenance support equipment statistical data and providing activities concerned with required reports and and prepunched/preprinted ESD and AMSE cards.

DATA PROCESSING

Data processing consists of performing certain job steps. Each of these steps usually requires a different type of machine to do the job. The number of steps required depends upon the particular application involved. The basic accounting principle consists of converting source data to punched cards, arranging the cards in the desired sequence, and printing reports from them.

The first step in a data processing application is to get the source data into a punched card. This is usually done by using a card punch machine. This machine is similar in operation to the standard typewriter; but, instead of printing when the keys are depressed, it punches holes in the cards representing numbers, letters, and characters. One type of card punch machine has a printing mechanism that allows for printing data on the card at the same time the card is being punched.

Numerical and alphabetical information is recorded in punched cards so that it can be read electrically by data processing machines. These machines can add, subtract, multiply, divide, copy, file cards, and print reports automatically. These functions take place after the machines read the information punched in the cards.

Each type of card is divided into fields, each representing a particular item or items of data. For example, a manhour accounting card has one field assigned for punching the organization code, another for punching the work center code, another for punching the name of the person, etc.

After cards have been punched, the data in them is checked for accuracy. There are two methods of doing this—visual verification and machine verification. Visual verification involves reading the data in printed cards, or on a prooflist, and comparing them with the contents of the source documents. Machine verification is performed by a mechanical card verifier. This machine is similar in appearance and operation to the card punch, except that instead of punching holes in a card, it reads the holes already in a card by a sensing mechanism, which passes through the punched holes when the proper keys are depressed. If the key that is depressed does not correspond to the code punched in the card, an error is indicated.

After verification, cards are seldom in the order in which they are used. To arrange the cards in desired sequence, a sorting machine is used. Sorting occurs one column at a time, and normally begins with the low order position of a field and continues to the high order position of the field. Cards can be sorted into either alphabetical or numerical sequence. In addition, certain cards may be selected or rejected, depending upon the setting of certain switches.

14285

The final step in a data processing application is usually the printing of a finished report. Accounting machines are designed to print the data contained in punched cards on continuous form paper at speeds far in excess of the fastest typist. Entire lines of data are printed across the form in one operation. Totals are accumulated and printed on the report along with the printed data.

In addition to the data processing steps previously discussed, data services also perform other steps in most accounting and processing procedures. Some of these include interpreting, reproducing, collating, and calculating.

In many instances it is desirable to have the punched card data printed on the card itself. This is especially true when cards must be handled outside of the machine installation. The job of the interpreter is to read the punched holes in a card and translate them into printed information across the face of the card.

Sometimes a duplicate deck of cards is required or information must be added into one deck from another. This could be accomplished by using a card punch machine; however, a much faster way is by use of a reproducing punch. All or any part of one card can be reproduced into another card, depending upon control panel wiring. In addition, common information can be gang punched into all cards. Reproducing punches are also used to punch totals accumulated in the accounting machine when the two machines are connected for a summary punch operation.

Certain jobs require matching two decks of cards, checking sequence of cards, merging groups of cards, or selecting certain cards. These jobs are performed by collators. By proper control panel wiring, these jobs can be performed singly or in conjunction with one another.

Calculating is the computing of a result by multiplication, division, addition, or subtraction. Any combination of these calculations can be performed by calculating punches. Factors to be calculated may be read from each card or from a series of cards, or they may be emitted by a device within the machine. The results of the calculation may be punched into each card or into a trailer card which follows a group.

Most data processing machines can perform more than one function. The machine must know what function it is to perform and how to handle the information it receives. A control panel is provided with most machines to enable the operator to give the machine the proper instructions for obtaining the desired results.

A control panel is a panel or board which, in most cases, can be removed from, or inserted into, the machine when desired. The panel has many small holes into which are inserted wires with special tips to control the functions of the machine. Each of these holes has a specific purpose or function. A control panel is similar in principle to a telephone switchboard. It completes electrical circuits through wires inserted in the panel.

The wiring of control panels for the preparation of MDCS reports requires considerable time and effort on the part of data services personnel. This is one reason why special reports should be requested only when the desired information is not available elsewhere.

Card Type Codes

Card type codes are two-position numerical codes used to identify the various punch cards that emanate from the source documents submitted to data services for processing. In many cases, a single source document can generate as many as three punched cards containing different information. Card codes are punched into columns 79-80 of the card.

For the most part, the source of data for the various punch cards is taken directly from submitted source documents; however, in some cases the punch card data is taken from machine produced reports.

Each card type code is listed in table 5-1 together with the card type and the data source from which the card is produced.

DATA DISTRIBUTION

Source documents received by data services are marked to indicate that all essential data has or has not been keypunched. This is usually accomplished by punching a hole in a specific location in the source document. Blocks on source documents that are not properly filled in or contain information that cannot be keypunched are encircled in red and returned to the originating activity for corrective action. Upon completion of the keypunch operation, all MDR source documents are returned to the originator for filing. Keypunched documents are usually returned on a daily basis.

After processing by data services, data is distributed to required activities. It is distributed in the form of reports or decks of keypunched EAM cards. Figure 5-1 depicts the flow of data from its origin to a Central Data Processing Facility (CDPF).

Selected information which has been collected by the maintenance and material management system is forwarded to a CDPF for inclusion in a data bank of maintenance and material information. Maintenance activities receive required data in the form of standard daily and monthly reports. Additional data may be received in special reports on an as-requested basis.

MAINTENANCE DATA REPORTS

The Support Action Forms, Maintenance Action Forms, and Technical Directive

UNIT 3 - TECHNIQUES OF SEWING

The content for Unit 3 has been divided into four topics covering the techniques related to pressing, constructing, altering, and repairing garments. Each topic follows the same format as the other units.

TOPIC 1: PRESSING TECHNIQUES

Competencies

- Select pressing equipment appropriate for the job.
- Use hand pressing equipment.
- Use machine pressing equipment.
- Press garments satisfactorily for show window or floor.
- Groom for personal safety.

Motivating Procedure

Display and assign a number to each pressing item listed below under Instructional Materials. Ask trainees to write the name and use of each item opposite the corresponding number on a sheet of paper. Discuss the correct name and use of each item.

Learning Experiences

- Demonstrate the use and care of hand and machine pressing equipment. Discuss the differences in the methods used for pressing various fabrics, garments, and garment parts. Use an information sheet on pressing garments as the basis for discussion. See Appendix F.
- Have trainees use various pieces of pressing equipment on sample garments. Display the pressed garments and evaluate the pressing skills of the trainees.
- Show pictures of clothing, hair styles, and jewelry on an opaque projector. Have trainees identify features that would create safety hazards when using various pressing equipment.

Instructional Materials

- Variety of garments
- Pictures of clothing, hair styles, and jewelry
- Ironing board
- Needle, sleeve, and seam boards
- Machine pressing equipment
- Steam iron and distilled water
- Variety of pressing clothes, hams, and mitts
- Point presser
- Pounding block or clapper
- Stiff brush

Compliance Forms completed by maintenance activities are forwarded to data services each working day. Through the media of automatic data processing machines, the information contained on these forms is keypunched into punch cards. At periodic intervals, the punched cards are sorted into logical sequence, listed or summarized in a readable format, and provided to the maintenance activity as maintenance data reporting system reports (MDR's).

These reports are designed to furnish management with selected statistics which are used to effectively monitor and direct the maintenance effort. In their entirety, the reports provide a comprehensive source of information relevant to the maintenance endeavor. Properly interpreted, the statistics contained in the reports indicate the extent of maintenance currently performed on the various types of equipment and components. Analysis of the pertinent data can reveal the existence of both favorable and adverse conditions prevalent within the maintenance activity.

A series of reports is prepared by data services for each 3-M oriented maintenance activity. These reports are separated into two categories—Standard Reports and Special Reports. Standard reports are those received by all maintenance activities on a recurring basis (daily, monthly, etc.), utilizing established formats and designed for specific uses. Special reports are those requested by individual maintenance activities on a one-time or continuing basis utilizing locally determined formats, and containing selected elements of data which would not ordinarily be desired by all maintenance activities.

STANDARD REPORTS

To insure the uniform reporting of basic maintenance data by all activities, standard reports are used. Compilation of selected elements of data in a specified format facilitates the preparation of maintenance summaries, allows comparison of statistics collected for similar type organizations and equipment, and simplifies the issuance of reporting instructions and mechanization procedures.

For the most part, standard reports are received on a monthly basis. These reports are delivered to the analysis division at specified times. Daily reports are normally delivered to the analysis division at the time the previous working day's documents are returned. The analysis division is responsible for internal organizational distribution of the machine reports.

A brief discussion of standard MDR's is contained in the following paragraphs.

Daily Production Report (MDR 1)

This report is intended for the work center supervisor and is a detailed listing, by work center, of all maintenance action, support action, and technical directive compliance forms submitted during the previous working day. Typical uses of the report by the work center supervisor are as follows:

1. The validity of forms submitted during the previous day can be checked. Any erroneous entries should be corrected by prescribed procedures.
2. The productive labor output of the work center can be monitored on a daily or cumulative basis.
